

The Long Shadow of Informality

Advance Edition

Challenges and Policies

Edited by
Franziska Ohnsorge and Shu Yu

Advance praise for *The Long Shadow of Informality: Challenges and Policies*

By definition, the informal economy is hard to study, especially in developing countries. This excellent book uses state-of-the-art methodologies and recently available data to measure and analyze informality in advanced economies and emerging market and developing economies. In particular, it explores the business cycles in the informal sector in 160 countries over the last 30 years; the study is the first one to show that cycles in the formal economy cause those in the informal economy. Contrary to the widespread stereotype that the informal sector is a buffer that helps to mitigate recessions in the formal sector, the informal sector's output moves in sync with the formal one, and informal employment does not increase during recessions. The book also produces the first analysis of the role of informality during the COVID pandemic. Informal economic activity is concentrated in labor-intensive service sectors and thus is especially vulnerable to social distancing and lockdowns. A rigorous, relevant and highly timely must-read for development scholars and policy makers.

Sergei Guriev

Professor of Economics, Sciences Po

Former Chief Economist, European Bank for Reconstruction and Development

Significant data gaps have previously limited our ability to thoroughly study the informal economy until now. The authors construct a novel and comprehensive dataset on informality, which allows them to unpack the complexity of the informal sector and its interaction with the formal sector. This timely book provides an invaluable knowledge resource for researchers and practitioners alike through an approach that balances rigorous quantitative and qualitative methods. The resulting policy recommendations offer compelling pathways for policy makers looking to address some of the main obstacles to formalization of the economies and accelerate economic development in the post-pandemic world.

Brahima Sangafowa Coulibaly

Vice President, Global Economy and Development

The Brookings Institution

This highly informative and timely book compiles various measures of the informal economy in a comprehensive global dataset. Its analysis of informality's most important correlates provides important insights and policy implications, written in highly accessible prose. Franziska Ohnsorge and Shu Yu have edited an authoritative source of reference for everyone interested in the informal economy. The questions raised in this book, and the answers given, make it essential reading for academics and policy makers alike.

Axel Dreher

Professor of International and Development Politics

Heidelberg University, Germany

Advance praise for *The Long Shadow of Informality: Challenges and Policies*

Informal economic activity has long been recognized as an important phenomenon in developing economies, one that poses a broad range of potentially serious policy challenges for both social and material wellbeing in those countries. Yet, for all the attention that various aspects of the informality phenomenon have received, there is no single comprehensive treatment of the topic that simultaneously considers the challenges of measuring informality, the identification of its causes in diverse settings, its specific social and economic consequences, and the range of context-specific policy measures that can potentially be adopted to address those consequences. Drawing on a comprehensive dataset covering a wide range of countries and time periods, this book fills that gap. I expect it to serve as a springboard for a more systematic and widespread integration of the problem of informality into development economics.

Peter Montiel

Fairleigh S. Dickinson, Jr. '41 Professor of Economics
Williams College

The COVID-19 crisis has exacerbated development challenges for many EMDEs, including as a result of disproportionate impacts on informal economic activity and therefore women, youth and lower-skilled workers. *The Long Shadow of Informality* provides important insights as to the extent, impact, and policy challenges posed by informality. By deepening our understanding of a key constraint to development this book can help guide appropriately tailored and comprehensive policy responses required to avoid a great divergence in economic prospects both within and between countries.

Ceyla Pazarbasioglu

Director of the Strategy, Policy and Review Department
International Monetary Fund

By its very nature, informality is hard to measure and even harder to address with policies. This book provides the most comprehensive treatment to date, combining different estimation methods, covering every developing region in the world, and spanning growth, business cycles, and sectoral issues. Being wide-ranging, the book will elicit debate on various topics. Thanks to this book, those debates can be based on solid empirical foundations.

Shanta Devarajan,

Professor of the Practice of International Development
Georgetown University

Foreword

In emerging market and developing economies (EMDEs), far too many people and small enterprises operate outside the line of sight of governments—in a zone where little help is available to them in an emergency such as the COVID-19 crisis. This “informal” sector constitutes more than 70 percent of total employment in these countries and roughly one-third of output.

Policy makers have long had good reasons to worry about this sector: Its participants are vulnerable even under normal conditions. Informal businesses rely heavily on family members and moneylenders for working capital, leaving them exposed to sudden income disruptions. These enterprises constitute 72 percent of firms in the services sector. Informal workers are predominantly women, and they are usually young and low-skilled. When they lose their jobs or suffer severe income losses, they often have no recourse to social safety nets.

COVID-19, however, has heightened the need for prompt and comprehensive action. The pandemic increased global poverty for the first time in decades—and it hit informal firms and informally employed workers particularly hard: they struggled to adjust to lockdowns and the shift to business connected over the internet. Data on this matter may not be fully available for some time, but the damage to households and firms in the informal sector poses a significant threat—to the global economic recovery and to long-term efforts to achieve green, resilient, and inclusive development.

Widespread informality hampers development progress in a variety of ways. It is broadly associated with weaker economic outcomes. Countries with larger informal sectors have lower per-capita incomes, greater poverty, less financial development, and weaker growth in output, investment, and productivity. GDP per capita in countries with above-average informality tends to be just one-quarter to one-third the GDP per capita of countries with below-average informality.

Moreover, informality curbs government revenues, constraining governments’ ability to provide services, conduct countercyclical policies, service debt, or implement crisis-response measures. Measured as a percentage of GDP, government revenues in EMDEs with above-average informality were 5 to 12 percentage points lower than those of EMDEs with below-average informality between 2000 and 2018. Not surprisingly, higher informality was also associated with lower public spending on education and health, contributing to the slower accumulation of human capital.

Yet the record shows informality *can* be tackled in EMDEs. In fact, it had been on a declining trend for decades before the onset of COVID-19. Between 1990 and 2018, on average, informality fell by about 7 percentage points of GDP to 32 percent of GDP. The decline partly reflected policy reforms: Over the past three decades, many EMDE governments implemented a wide range of policy reforms either to increase the benefits of formal-sector participation or to reduce the costs of

such activities. These included tax reforms, reforms to increase access to finance, and stronger governance.

The key, however, is to recognize informality as a phenomenon that reflects broad-based underdevelopment—rather than a challenge that can be considered in isolation. For that reason, measures to address informality need to be equally broad-based.

This book offers the first detailed road map to cope with informality for policy makers in developing countries. Above all, it underscores the need for an encompassing approach. A comprehensive policy package tailored to country circumstances offers the greatest chance of success. Depending on country circumstances, such a package should include the following components:

- *Improvements in macroeconomic policies, governance, and business climates.* In the past three decades, EMDEs have made progress in reducing tax burdens, improving governance and regulatory quality, and enhancing access to finance, education, and public services. These actions have helped reduce the extent of informality, but additional reforms are needed to make further progress.
- *Streamlined tax regulation and administration and improved public service delivery.* Policies aimed at invigorating private sector activity—such as measures to increase labor market flexibility and streamlining regulatory frameworks for firm start-up—have also been associated with declines in informality.
- *Attention to unintended consequences of policy reforms.* For instance, trade liberalization that raised competition in the tradable sector has been associated with greater informality in the short run—unless it is accompanied by measures that increase labor market flexibility.
- *Acceleration of financial sector development.* Such development has been associated with declining informality—because it reduces the average cost of access to external financing and creates incentives for firms to invest in higher-productivity projects and join the formal sector.
- *Campaigns to expand public awareness.* Reductions in informality have tended to be greater for reforms that have been accompanied by business development and training programs, public awareness campaigns, and stronger enforcement.

Rebuilding the global economy in the aftermath of COVID-19 will mean mobilizing every available reserve of productive power to generate green, resilient, and inclusive development. That effort must begin now—and it cannot succeed without full consideration of the challenges of the informal sector.

Mari Pangestu
Managing Director of Development Policy and Partnerships
The World Bank

Executive Summary

Informal activity is widespread in emerging market and developing economies (EMDEs). In the average EMDE, informal economic activity accounts for about one-third of output and more than two-thirds of employment (chapter 2). The phenomenon extends across all EMDE regions.

Widespread informality has long been associated with a whole host of development challenges (chapter 4). Most prominently, more widespread informality has been associated with significantly poorer governance and greater lags in achieving every dimension of the Sustainable Development Goals. Countries with larger informal sectors tend to have less access to finance for the private sector, lower labor productivity, slower physical and human capital accumulation, and smaller fiscal resources. Informality is associated with higher income inequality and poverty and less progress toward the Sustainable Development Goals.

Informal firms are, on average, less productive than formal ones because they tend to employ more low-skilled workers; have more restricted access to funding, services and markets; and lack economies of scale. Informal workers tend to be paid less than formal workers, in part because they are lower-skilled. Female and young workers make up a disproportionate share of workers in the informal sector.

Pervasive informality is particularly pernicious at the current juncture. In the severe global recession caused by the COVID-19 pandemic, the informal sector has been hit hard by the lockdowns and changes in consumer behavior triggered by the pandemic. Informal firms account for almost three-quarters of firms in the services sector, compared with one-third of firms in the manufacturing sector. With low incomes and little savings to fall back on, informal workers struggle to comply with lockdowns and government support program often cannot reach them.

Going forward, widespread informality may hold back the recovery to a green, inclusive, and resilient development path. Countries with high informality struggle to muster the fiscal resources to support economic activity; to implement effective monetary policy in a shallow financial system; and to generate informal-sector income growth or formal-sector employment in a recovery.

Government revenues in EMDEs with above-average informality are about 5-12 percentage points of GDP below those in other EMDEs, and so are their expenditures. This constrains governments' ability to develop fiscal support packages that can help bring the pandemic under control and generate a robust recovery. Indeed, in 2020-21, EMDEs with above-median informality

implemented discretionary fiscal support packages that were only three-quarters the size of those in EMDEs with below-median informality.

In countries with widespread informality, shallow financial systems limit the reach and effectiveness of monetary policy. In EMDEs with above-median informality, domestic credit to the private sector is only one-third of GDP—significantly less than in other EMDEs where it is more than one-half of GDP—and many firms do not rely on the formal financial system at all. For example, in EMDEs with above-median informality, only 19 percent of firms can access bank financing for their investment needs, significantly less than the 29 percent of firms in other EMDEs.

If history is any guide, large informal sectors will dampen the recovery. Historically, informal-economy output and, hence, incomes have fluctuated with formal-economy output, but less than proportionately (chapter 3). For every 1 percentage point increase in formal-economy output, informal-economy output has risen only by 0.4-0.8 percentage point over the following year. While this muted co-movement dampened past recessions, it also held back past recoveries.

Moreover, informal employment historically has been largely unresponsive to formal-economy business cycles. This suggests that workers do not easily switch between formal and informal employment; instead, once they are informally employed, they tend to expand or curtail their working hours with the business cycle. It also suggests that whatever increase in informal employment the COVID-19 pandemic has induced—and we will not have the data to know for sure for many months—may not be unwound in the recovery from the pandemic.

This book offers a wide menu of policy options to address these challenges associated with informality. Improved access to education, markets, and finance can help informal workers and firms become sufficiently productive to move to the formal sector. Labor productivity in EMDEs with above-median informality is less than a third of the level in other EMDEs. This in part reflects low human capital: In EMDEs with above-median informality, the average number of schooling attained amounts to 5-6 years—1-3 years less than in other EMDEs.

In addition, improved governance and business climates and streamlined—but well-enforced—regulations can lower the cost of operating formally and increase the cost of operating informally. In these dimensions, EMDEs with high informality clearly lag those with low informality. For example, the average score on bureaucracy quality in EMDEs with above-median informality is one third lower than in other EMDEs.

While helping to lower informality, such policy measures also spur growth more broadly. To protect vulnerable groups, they may need to be accompanied by stronger basic social safety nets (chapter 6).

These options are most likely to be effective when they follow two principles.

First, reform packages need to be comprehensive. Over the past several decades, many EMDE governments implemented policies at the microeconomic level and found that the implications for informality were more benign when these reforms were implemented in a supportive institutional and macroeconomic environment. For instance, trade liberalization programs that raised real wages and reduced firms' profitability in the tradable sector were associated with greater informality in the short term—unless they were accompanied by higher labor market flexibility and more skilled labor force.

Second, reform packages need to be tailored to country circumstances, informed by the drivers of—and challenges posed by—informality and carefully tailored to country circumstances. In Sub-Saharan Africa, South Asia, and the non-Gulf Cooperation Council economies of the Middle East and North Africa, for example, general education and training programs to raise human capital could be prioritized (chapter 5). In Latin America and the Caribbean, reducing particularly high tax and regulatory costs to businesses could incentivize firms to join the formal sector. In Europe and Central Asia, improving government effectiveness and reducing corruption could be policy priorities.

Acknowledgments

This book is a product of the Prospects Group in the Equitable Growth, Finance and Institutions (EFI) Vice Presidency. The project was managed by Franziska Ohnsorge and Shu Yu, under the general guidance of M. Ayhan Kose. Ayhan's constant support, thorough and carefully considered feedback, analytical insights, and dedication to the success of this book immeasurably raised the quality of the book.

The core team underlying the project included Salvatore Capasso, Ceyhun Elgin, Sergiy Kasyanenko, Yoki Okawa, Cedric Okou, and Dana Vorisek. The book reflects their original insights, analytical depth, and painstakingly careful work. The chapter on regional dimensions of informality was prepared by Gene Kindberg-Hanlon, Wee Chian Koh, Yoki Okawa, Temel Taskin, Ekaterine T. Vashakmadze, Dana Vorisek, and Lei Sandy Ye, who brought their extensive regional knowledge to the subject.

Many colleagues in the Prospects Group provided detailed comments and feedback during various stages of the project, including Carlos Arteta, Sinem Kilic Celik, Justin Damien Guenette, Jongrim Ha, Gene Kindberg-Hanlon, Patrick Alexander Kirby, Peter Stephen Oliver Nagle, Cedric Okou, Franz Ulrich Ruch, Naotaka Sugawara, Temel Taskin, Dana Vorisek, and Collette Mari Wheeler.

This book is built upon the foundation of chapter 3 of the 2019 January *Global Economic Prospects* report. The early work benefited from invaluable discussions with Shanta Devarajan, Pinelopi Goldberg, Ceyla Pazarbasioglu, William Maloney, and Norman Loayza. The team also received helpful comments and suggestions from James Brumby, Anna Custer, Mark Andrew Dutz, Margaret Grosh, Truman Packard, and Marijn Verhoeven. In addition, many World Bank Group colleagues provided extensive feedback at different stages of the project, including during the institution-wide review of our work.

The book benefited from constructive comments and feedback received during both preparation and production stages. The team is grateful to many scholars who provided extensive comments on chapter drafts: Salvatore Capasso, Ugo Panizza, and Gabriel Ulyssea. The team is grateful as well to many World Bank colleagues who provided comments on the drafts during a final review process, including Mohammad Amin, Kevin Carey, Ergys Islamaj, Gerard Kambou, and Guillermo Javier Vuletin. The team benefited greatly from consultations and discussion with Mariam Dolidze, Andreja Marusic, Evgenij Najdov, Hulya Ulku, and Gabriel Zaourak. The team owes a particular debt of gratitude to Graham Hacche, who painstakingly edited all the chapters.

The team is also thankful to the organizers and participants at various seminars and conferences held in 2019-20, who provided valuable early feedback on various chapters of the book: Bank of England; De Nederlandsche Bank; European Central Bank; European Bank for Reconstruction and Development (EBRD); Organization for Economic Co-operation and Development (OECD); European Commission; ETH Zurich; Heidelberg University; the 7th International Monetary Fund Statistical Forum; the 2019 Fall Midwest Macroeconomic Meetings; and the 2020 Congress of the European Economic Association.

Zhuo Chen, Hrisyana Doytchinova, Maria Hazel Macadangdang, Jinxin Wu, Lorez Qehaja, Arika Kayastha, Shijie Shi, and Xinyue Wang provided outstanding research assistance. Yiruo Li, Zhuo Chen, Shituo Sun, Jinxin Wu, and Liwei Liu helped compile the database in the early stages of the project. Thanks also to Roberto Crotti and Margareta Drzeniek, who shared valuable data with us.

The team is indebted to colleagues who supported us throughout the production process: Maria Hazel Macadangdang for guiding us through the steps from beginning to completion of the book; Adriana Maximiliano for designing and typesetting; and Graeme B. Littler for editorial and website support. Abdennour Azeddine provided excellent technology support. The team also appreciate the great support from many colleagues in External and Corporate Communications Vice Presidency of the Bank, including Alejandra Viveros, Joseph Rebello, and Torie Smith, and colleagues from the Sustainable Development Goals (SDG) Fund team, including Juliana Knapp and Lisa Maria Castro.

The Prospects Group gratefully acknowledges financial support from the World Bank Group Partnership Fund for the Sustainable Development Goals (SDG Fund) and the Research Support Budget (RSB) overseen by the Research Committee of the Development Economics Vice-Presidency (DECRG).

*The current crisis is a sharp contrast from the recession of 2008. ...
This time, the economic downturn is broader, much deeper, and has
hit informal sector workers and the poor, especially women and
children, harder than those with higher incomes or assets.*

President of
World Bank Group

CHAPTER 1

Overview

Motivation

By now, the economic damage of the COVID-19 pandemic has been extensively documented. The pandemic and associated containment measures plunged the global economy into a severe contraction. Global output shrank by more than 4 percent in 2020, with output in emerging market and developing economies (EMDEs) contracting by about 3 percent, the group's first annual contraction in more than sixty years (World Bank 2021). Over the past century and a half, the pandemic-driven global recession was the deepest since the Second World War and featured the largest fraction of economies with declines in per capita output since at least 1870 (World Bank 2020a). The decline in per capita incomes during the pandemic has pushed millions of people into extreme poverty since the beginning of the pandemic.

While the pandemic has been simply devastating, its impact has been particularly severe on the informal sector (World Bank 2020a). With a prominent presence in the services sector, informal workers were more likely to lose their jobs or suffer severe income losses during lockdowns (Balde, Boly, and Avenyo 2020; Schotte et al. 2021). A large informal sector is also associated with poorer access for many to public health and sanitation facilities, making it harder to contain the spread of the pandemic (World Bank 2020a). Informal workers are largely excluded from formal social safety nets and have low incomes and limited buffers such as savings or access to government support programs.

Informality has been associated with broader development challenges since long before the pandemic (World Bank 2019). In EMDEs, the informal sector accounts for about a third of GDP and more than 70 percent of employment (of which self-employment is more than a half; figure 1.1). Regardless of the nature and causes of informality, countries with larger informal sectors tend to have less access to finance for the private sector, lower labor productivity, slower physical and human capital accumulation, and smaller fiscal resources (Docquier, Müller, and Naval 2017; La Porta and Shleifer 2014). Informality is also associated with higher income inequality and poverty and less progress toward the Sustainable Development Goals (SDGs; Chong and Gradstein 2007; Loayza, Servén, and Sugawara 2010). The informal sector is, on average, less productive than the formal sector because it tends to employ more low-skilled workers, have more restricted access to funding, services and markets, and lack economies of scale (Amaral and Quintin 2006; Loayza 2018).

Note: This chapter was prepared by Franziska Ohnsorge and Shu Yu. Research assistance was provided by Hrisyana Doytchinova and Maria Hazel Macadangdang.

FIGURE 1.1 Informality: Main features

The informal sector accounts for about a third of GDP and more than 70 percent of employment (of which self-employment is more than a half) in EMDEs. A large informal sector is often associated with lack of development and weak governance as well as greater poverty and income inequality.

A. Share of informal output and self-employment

B. Informality: output and employment shares, and perceptions

C. Informality by EMDE region

D. Per capita incomes and informality

E. Informality, poverty, and income inequality

F. Governance in EMDEs with high and low output informality

Sources: International Country Risk Guide (ICRG); International Labour Organization; World Bank (World Development Indicators); World Economic Forum; World Values Survey.

Note: EAP = East Asia and Pacific; ECA = Europe and Central Asia; EMDEs = emerging market and developing economies; DGE = dynamic general equilibrium model-based estimates in percent of official GDP; LAC = Latin America and the Caribbean; Labor force w/o pension = the share of labor force without pension; MIMIC = multiple indicators multiple causes model-based estimates in percent of GDP; MNA = Middle East and North Africa; SAR = South Asia; SSA = Sub-Saharan Africa; WVS = World Values Survey estimates (1-10; a higher value means that cheating on taxes is more justifiable); WEF = World Economic Forum estimates (1-7; 7 = most informal).

A. Unweighted averages. Self-employment shares with missing value interpolated in EMDEs for earlier years and filled using the latest available observation in recent years. They are proxies for informal employment. World averages between 1990-2018 are in orange.

B. Unweighted averages for latest available year. Whiskers are +/-1 standard deviation. Measures are grouped into output informality, employment informality, and perception-based informality. Data on informal employment are for EMDEs.

C. Bars show simple average shares of DGE-based informal output (in blue; self-employment shares in red) for 1990-2018.

D. GDP per capita in constant 2010 U.S. dollars. Unweighted average for EMDEs with above-median ("High informality") and below-median share of (DGE-based) output informality ("Low informality"). *** = statistically significant difference at the 10 percent level.

E-F. Bars are unweighted average for EMDEs with above-median ("High informality") and below-median share of (DGE-based) output informality ("Low informality") for 1990-2018. Poverty headcount measures the percent of population living on \$1.90 a day or less (2011 PPP). Whiskers are 90 percent confidence intervals.

Realizing the growth potential of the resources employed by the informal sector is a pressing matter, as EMDEs rebound from the current recession. Policy actions can unleash the growth potential of the informal sector's resources by promoting their transfer to the formal sector, and providing better public services and social safety nets to protect vulnerable groups who remain in the informal sector. These policy interventions are even more important now since the pandemic is expected to leave long-lasting scars on the global economy, including less physical capital because of lower investment, erosion of the human capital of the unemployed, and a weakening of global trade and supply linkages (World Bank 2020a). These effects may well lower the levels and growth rates of potential output and labor productivity over a long period.

Against this backdrop, this book presents the first comprehensive study of informality—of its extent, evolution and consequences, and of the policy options to address its challenges. The book makes several contributions to an already-large literature.

Comprehensive assessment. The book brings together a wide range of topics related to the informal economy, ranging from measurement issues to policy options. In contrast, earlier work typically examines only one of the dimensions covered in this book, such as the advantages and drawbacks of existing informality measures, the cyclical features of the informal sector, the developmental implications of informality, or examples of policy impacts.¹

Regional emphasis. The book brings a regional dimension to the discussion of informality in EMDEs (chapter 5). Existing studies often group all countries together (Medina and Schneider 2018, 2019) or focus on a few specific regions or countries (Loayza, Servén, and Suguwara 2010; Perry et al. 2007). To allow comparisons across all six EMDE regions, the book utilizes a comprehensive data set that covers more than 120 EMDEs. In addition, the two chapters in Part II include only EMDEs in the analysis to avoid the results being driven by differences in the nature of informality between advanced economies and EMDEs.

Analysis of the implications of COVID-19. The book provides an analysis of the impact of COVID-19 in EMDEs with pervasive informality (chapter 2). This links the features of the informal sector with the health and economic consequences of COVID-19. It also highlights the policy challenges arising from informality when EMDEs have been facing the consequences of the deepest global recession since the Second World War.

Multiple approaches. The book uses a wide range of approaches and synthesizes findings based on multiple measures of informality. The literature on informality has mostly relied on either survey-based estimates of informality or model-based estimates

¹ See Medina and Schneider (2018) and Schneider, Buehn, and Montenegro (2010) for discussions of the advantages and drawbacks of informality measures; Bosch, Goni, and Maloney (2007), Fiess, Fugazza, and Maloney (2010), and Loayza and Rigolini (2011) for the cyclical features of the informal sector; La Porta and Shleifer (2014), Loayza (2016), and Loayza, Servén, and Suguwara (2010) for the developmental implications of informality; and Dix-Carneiro et al. (2021) and Ulyssea (2020) for examples of policy impacts.

and examined informality in terms of either output or employment.² The book examines three dimensions of informality, including output, employment, perceived level of informality, and uses a combination of informality measures to overcome the limitation of each measure (chapter 2). In addition, various empirical strategies are employed to address the specific questions posed in different chapters. The study is the first to conduct a Bayesian Model Averaging (BMA) estimation—designed to capture model uncertainty—to identify robust correlates of informality, and a meta-analysis of published empirical studies to estimate the wage gap between formal and informal workers (chapter 4).

For the purposes of this study, informality is defined as market-based legal production of goods and services that is hidden from public authorities for monetary, regulatory, or institutional reasons (Schneider, Buehn, and Montenegro 2010).³ Output informality is proxied by dynamic general equilibrium (DGE) model-based estimates in percent of GDP, and employment informality is proxied by self-employment in percent of total employment, unless otherwise specified (chapter 2).

Key findings and policy messages

Using a comprehensive database of multiple informality measures, this book examines the main characteristics of the informal economy, discusses its developmental implications, and presents a range of policy options to address issues associated with it.

Features of informal activity

Informality is associated with underdevelopment more broadly (La Porta and Shleifer 2014). While the informal economy accounts for one-fifth of GDP and 16 percent of employment in the advanced economies, it accounts for one-third of GDP and 70 percent of employment in an average EMDE (of which self-employment accounts for more than a half, chapter 2). Both informal output and employment have declined since 1990, especially in EMDEs. Thus, on average in EMDEs, the share of informal output in GDP fell by about 7 percentage points (to 32 percent), and the share of self-employment in total employment declined by about 10 percentage points (to 36 percent) over 1990-2018. These declines were broad-based.

There is wide heterogeneity in informal activity among EMDEs and EMDE regions. For example, in 2018, in terms of output, the informal economy ranged from around 10 percent of GDP to 68 percent of GDP, while in terms of employment, self-employment ranged from near-zero to 96 percent of total employment. On average among the EMDE regions, the informal economy's output share is highest in Sub-Saharan Africa

² Studies like Fajnzylber, Maloney, and Montes-Rojas (2011) and Amin (2021) relied on survey-based estimates, while studies like Dreher and Schneider (2010) and Elgin, Elveren, and Bourgeois (2020) utilized model-based estimates. Bajada (2003), Dell'Anno (2008), and Giles (1997) examined output informality, while studies like Fiess, Fugazza, and Maloney (2010) and Loayza and Rigolini (2011) examined employment informality.

³ The definition and classification of informality are context-specific. See chapter 2 for various other definitions.

(SSA), Europe and Central Asia (ECA), and Latin America and the Caribbean (LAC). The share of self-employment, however, is highest in Sub-Saharan Africa (SSA), South Asia (SAR), and East Asia and Pacific (EAP; chapter 5). While all EMDE regions have witnessed declines in informality between 1990 and 2018, declines in output informality have been largest in East Asia and Pacific (EAP) and South Asia (SAR) while declines in employment informality have been largest in the Middle East and North Africa (MNA) and Sub-Saharan Africa (SSA). In Europe and Central Asia (ECA), employment informality has remained broadly unchanged, while in Latin America and the Caribbean (LAC) it has risen.

The pandemic's toll in EMDEs with widespread informality

COVID-19 has taken a particularly heavy toll on participants in the informal sector. Several features of the informal sector cause its participants to suffer more severe economic losses than their formal counterparts during lockdowns and provide support to informal workers and firms.

Characteristics of informal workers. Workers in the informal sector tend to be lower-skilled and lower-paid, with less access to finance and social safety nets, than workers in the formal sector (Loayza 2018; Perry et al. 2007). They often live and work in crowded conditions and conduct all transactions in cash—factors that promote the spread of disease (Chodorow-Reich et al. 2020; Surico and Galeotti 2020). The absence of social safety nets makes informal workers less able to afford to adhere to social distancing requirements, which undermines policy efforts to contain the spread of COVID-19 (Loayza and Pennings 2020). In EMDEs with the most pervasive informality, people are more likely to be driven into poverty if they have to make direct out-of-pocket payments for health-care emergencies.

Characteristics of informal firms. Informal firms tend to be labor-intensive and more prevalent in the services sector. Such firms have been particularly hard-hit by measures to curtail social interactions.⁴ In EMDE service sectors, about 72 percent of firms are informal, compared with 33 percent in manufacturing sectors (Amin, Ohnsorge, and Okou 2019). Informal firms rely on internal funds, making them especially vulnerable to disruptions to cashflows caused by mitigation and other control measures (Farazi 2014).

Broader development challenges. A larger informal economy is associated with weaker economic, fiscal, institutional, and development outcomes. GDP per capita in countries with above-median informality is about one-quarter that of countries with below-median informality. EMDEs with more informality lack adequate public health systems, access to clean water and handwashing facilities. Government capacity to mount an effective policy response to pandemics is more limited (box 2.1). In addition, in countries with widespread informality, governments have limited resources and the

⁴ See Benjamin and Mbaye (2012); Panizza (2020); and Surico and Galeotti (2020).

administrative structures in place to effectively deliver well-targeted relief to those most in need (Muralidharan, Niehaus, and Sukhtankar 2016).

Development challenges associated with informality

EMDEs with pervasive informality face a wide range of development challenges (chapter 4). Countries with larger informal sectors have lower per capita incomes, greater poverty, less developed financial sectors, and weaker growth in output, investment and productivity. People living in EMDEs with more widespread informality suffer from greater prevalence of hunger, poorer health and education, and greater gender inequality. Informal firms are less productive than their formal counterparts, while informal workers are paid less than their formal counterparts due to their lack of work experience and education.

Policy challenges associated with informality

Underdevelopment. More pervasive informality is associated with significantly lower government revenues and expenditures, less effective institutions, more burdensome tax and regulatory regimes, and weaker governance (chapters 4 and 6). Weaknesses in governance and revenue collection constrain the provision of public services, contributing to poorer development outcomes and poorer access to, and lower-quality, infrastructure. Limited fiscal resources constrain the government's ability to provide social safety nets during recessions, as exemplified during COVID-19, and to use policy measures to smooth business cycles.

Cyclical features of the informal economy. Additional challenges are posed by the behavior of informal economic activity through business cycles. While informal employment remains broadly stable through business cycles in the formal economy, informal output is mildly procyclical, responding positively, although less than proportionately, to formal-economy output swings (chapter 3). As a result, the informal sector appears to dampen output losses during downturns—but also seems to moderate output gains during upturns, as well as the impact of macroeconomic stabilization policies.

Tackling informality

The decline in informality over the past three decades has been accompanied by improvements in policy climates in EMDEs. Most EMDEs have reduced tax burdens, enhanced access to finance, education, and public services, and improved governance and regulatory quality. Meanwhile, some policy measures have sometimes had unintended consequences. A coherent reform strategy calls for well-integrated reforms that complement each other and address the complexity of informality.

Need for comprehensive reform packages. Many EMDE governments implemented policies at the microeconomic level and found that the implications for informality were more benign when these reforms were implemented in a supportive institutional and

macroeconomic environment. For instance, trade liberalization programs that raised real wages and reduced firms' profitability in the tradable sector were associated with greater informality in the short term—unless they were accompanied by higher labor market flexibility and more skilled labor force (chapter 6).

Need for tailored reform packages. Country experiences suggest the need for a comprehensive development strategy that is informed by the drivers of, and challenges posed by, informality and carefully tailored to country circumstances. Each reform component requires a diagnosis of the country's current situation, followed by specific reforms to address the main weaknesses associated with and underlying sources of informality. In SSA, SAR, and the non-GCC economies of MENA, for example, general education and training programs to raise human capital could be prioritized (chapter 5). In LAC, reducing particularly high tax and regulatory costs to businesses could incentivize firms to join the formal sector. In ECA, improving government effectiveness and reducing corruption could be policy priorities.

The success of implementation also depends on careful monitoring of potential unintended consequences and a supportive macroeconomic, political and institutional environment. The latter ensures the political and fiscal viability of the implementation and reduces the transition costs for workers moving from the informal sector to the formal sector.

Policies that seek to improve fiscal operations, such as strengthened tax administration or streamlined tax regulations, can be associated with lowering informality in some economies. Separately, policies that aim at invigorating private sector activity and productivity and leveling the playfield for all workers and firms, particularly measures to make the labor market more flexible, the regulatory framework more adaptable, and governance more effective, can lower informality and/or improve the working conditions in the informal sector. Finally, supportive macroeconomic and social policies (such as enhancing public service and social protection) can ease the implementation of these reforms and facilitate a smoother transition from the informal sector to the formal sector.

These policy measures can help lower informality while also spurring growth more broadly. They need to be accompanied by strengthening the basic social safety nets to preserve incomes of vulnerable groups. Disruptions to formal activity from interventions to lower informality could be mitigated by reforms to increase labor and product market flexibility.

Synopsis

The remainder of this introduction summarizes the main messages of each chapter. For each chapter, the main questions, contributions to the literature, and analytical findings are presented. These summaries are followed by a brief discussion of future research directions.

Part I: Characteristics of the informal economy

Part I examines the evolution of informality, as well as its main correlates. Chapter 2 documents the main features of, and trends in, informality over the past three decades, with an emphasis on EMDEs. Chapter 3 explores the cyclical features of informality.

Chapter 2. Understanding the Informal Economy: Concepts and Trends

By its nature, informality is difficult to observe and measure. Chapter 2 introduces a comprehensive database of informality measures and describe the evolution of informality across EMDEs. In these economies, on average, informal-economy output accounts for about one-third of GDP and informal employment constitutes about 70 percent of total employment (of which self-employment accounts for more than one-half). In some countries in Sub-Saharan Africa (SSA), informal employment accounts for more than 90 percent of total employment and informal output for as much as 62 percent of official GDP (ILO 2018).

Against this backdrop, this chapter reviews conceptual and measurement issues regarding the informal economy and documents its main features across countries and over time. Specifically, it addresses the following questions:

- How is the informal economy defined?
- How has informality evolved?
- What are the features of the informal economy?

Contributions. The chapter makes the following contributions to the literature. *First*, it compiles a comprehensive database of measures of informality developed in the literature, with a focus on measures that have broad cross-country and long historical coverage. The resulting dataset combines 12 cross-country databases and data provided by almost 90 national statistical agencies.⁵ *Second*, the chapter presents two applications of this database. It distills stylized facts about the informal economy, such as its size and evolution over time, using a wide range of informality measures, and tests the consistency of these stylized facts across these measures. In addition, the chapter documents the cyclical behavior of the informal economy, such as the duration and amplitude of its recessions and recoveries.

Main findings. *First*, the chapter presents a careful analysis of the advantages and drawbacks of existing informality measures. Most of the macroeconomic literature on

⁵ Official GDP statistics often make an adjustment for informal activity. However, the magnitude of such adjustments is rarely specified. In a survey in 2008, national statistical agencies for about 40 mostly advanced economies or economies in transition reported adjusting their official GDP statistics by amounts ranging from 0.8 to 31.6 percent for activity in the non-observed economy (NOE), which is a broader concept than the informal economy (United Nations 2008). For all reporting economies, the adjustments were well below those suggested by the measures of informality presented in this study.

informality has relied solely on either survey-based or model-based estimates. Survey-based measures can cover many dimensions of the informal economy, but they suffer from poor country and year coverage (especially for EMDEs), reporting bias, and lack of consistency in survey methods.⁶ Indirect, model-based measures of informal output stand out in their potentially comprehensive country and year coverage and their consistent economic meaning, but they rely on strong assumptions. The chapter highlights the circumstances in which the various individual informality measures could be particularly helpful. This adds to earlier literature that has focused on the limitations of a narrow range of estimation methods.

Second, the chapter argues that the combination of direct, survey-based indicators with indirect, model-based estimates can overcome the limitations of each. Informal employment measures tend to cover either the number of hours worked per day in informal employment (“intensity” of participation in informal employment) or, regardless of the number of hours worked per day, the presence of informal employment (“extent” of participation; Meghir, Narita, and Robin 2015). Since the extent of participation in the informal economy and its intensity may evolve differently, informal production may move asynchronously with informal employment.⁷ Thus measures of informal output are an important complement to measures of informal employment.

Third, the chapter distills the main features of the informal economy and its evolution over time. Three different dimensions of informality are identified in the chapter: output, employment, and perception. Cross-country rankings of informal output and employment are typically consistent. Both output and employment measures of informality have trended downward since 1990 and have shown some cyclicity (figure 1.2). In contrast, perception-based measures have tended to be highly stable over time and could, therefore, be more appropriate for cross-country comparisons.

Fourth, the chapter is the first study that documents the cyclical features of the informal sector in both advanced economies and EMDEs. Cyclical features of informal economy output do not differ statistically significantly from those of formal economy output. Like the formal economy, the informal economy undergoes larger output movements over the business cycle in EMDEs than in advanced economies. Steeper recessions and stronger recoveries in EMDEs contribute to greater output volatility, as shown in previous studies (Aguiar and Gopinath 2007). Meanwhile, unlike formal employment, which contracts significantly in advanced economies during formal economy recessions, informal employment in both advanced economies and EMDEs appears largely acyclical during informal output business cycles. This may reflect wage movements or changes in

⁶ Survey-based informality measures are based on income data from surveys or audits that differ from incomes declared for tax purposes (Binelli and Attanasio 2010; McCaig and Pavcnik 2015), or earnings from firm surveys (Almeida and Carneiro 2012; Putnins and Sauka 2015).

⁷ For example, during a recession, labor may move from the formal sector to the informal sector and raise participation in the informal economy (Loayza and Rigolini 2011). However, due to the fall in demand, the intensity of participation, captured by the number of hours worked in informal employment, may remain the same or even drop, and informal output may decline.

FIGURE 1.2 Informality: Extent and evolution

Informality is more pervasive in emerging market and developing economies (EMDEs) than in advanced economies. While there remains wide cross-country heterogeneity in informality among EMDEs, informality has generally declined over the past three decades.

A. Informal share of output

B. Informal share of employment

C. Informal share of output, 1990-2018

D. Informal share of employment, 1990-2018

E. Informality: output and employment shares, and perceptions

F. EMDEs with downward trend in informality, 1990-2018

Source: World Bank.

Note: See chapter 2 for details on data definitions. Output informality is measured by dynamic general equilibrium (DGE) model-based estimates on informal output in percent of official GDP. In B and D, Informal employment is proxied by self-employment (SEMP) in percent of total employment. EMDEs = emerging market and developing economies; Labor force w/o pension = the share of labor force without pension; MIMIC = multiple indicators multiple causes model-based estimates on informal output in percent of GDP; WEF = World Economic Forum estimates (1-7; 7 = most informal); WVS = World Values Survey estimates.

A.B. Bars show simple group averages (world, advanced economies, and EMDEs) over the period 2010-2018; -1 and +1 standard deviations (SD) shown in orange whiskers.

B.D. Missing data for self-employment in percent of total employment are interpolated in EMDEs for earlier years and filled using the latest available observation in recent years.

C-D. Lines show simple group averages.

E. Unweighted averages for latest available year. Whiskers are +/-1 standard deviation. Measures are grouped into output informality, employment informality, and perception-based informality.

F. Based on country-specific linear regressions of the share of informality by each of the four measures of informality with a sufficiently long time-dimension. Bars show the share of EMDEs for which the time trend is statistically significantly negative (at least at 10 percent level). Orange line indicates 50 percent.

intensity (measured as number of hours worked per day) in labor markets, which may bear the brunt of adjustment during business cycles (Guriev, Speciale, and Tuccio 2019; Meghir, Narita, and Robin 2015).

Chapter 3. Growing Apart or Moving Together? Synchronization of Informal- and Formal-Economy Business Cycles

Chapter 3 investigates the role of the informal economy as a potential dampener of business cycles that policy makers need to take into account when deciding on countercyclical macroeconomic policies. If the informal economy expands while the formal economy contracts, it may support household incomes and consumer demand during economic downturns and serve as a safety net for the economy (Loayza and Rigolini 2011). If the informal economy expands during expansions in the formal economy, it could function as an auxiliary “growth engine” during economic expansions (Chen 2005; Dell’Anno 2008; Meagher 2013).

In theory, the cyclical relationship between informal and formal sectors is ambiguous.⁸ Some theoretical models have shown that the informal economy may absorb a larger share of workers as jobs become scarce in the formal sector during economic downturns (Bosch, Goni and Maloney 2007; Dix-Carneiro et al. 2021; Loayza and Rigolini 2011). Such behavior by the informal sector could facilitate economic recovery—by providing a potential supply of labor to the formal sector and preventing the hysteresis costs on unemployment—if re-entry into the formal sector is possible when the formal economy returns to expansion (Colombo, Onnis, and Tirelli 2016; IMF 2017).

In contrast, if informal firms provide services, as well as final and intermediate goods, to the formal sector, a positive correlation may emerge between formal and informal sector activity (Arvin-Rad, Basu, and Willumsen 2010; Lubell 1991). In addition, informal-economy income can support formal-economy demand (Docquier, Muller, and Naval 2017; Gibson 2005; Schneider 1998). In these circumstances, the informal economy would amplify macroeconomic fluctuations (Restrepo-Echavarría 2014; Roca, Moreno, and Sánchez 2001).

Empirical evidence on the behavior of the informal economy over the business cycle is also inconclusive. This has been attributed partly to different country characteristics and the roles of different economic shocks.

In light of these observations, this chapter addresses the following questions:

- What conclusions does the literature offer about the cyclical behavior of the informal economy?
- How synchronized are movements in informal and formal economies?

⁸ Some early works suggested that the degree of cyclicity of the informal economy depends on the measure of informality used and country characteristics.

- Do fluctuations in formal economy output “cause” fluctuations in output or employment in the informal economy?

Contributions. The chapter makes three contributions to the literature. *First*, it is the first analysis of the cyclical linkages between formal and informal sectors using data for multiple measures of informality for a large set of economies—about 160 economies, comprising 36 advanced economies and about 124 emerging markets and developing economies (EMDEs). It covers a long, recent period—1990-2018—and is the first study of the behavior of both output and employment in the informal economy: previous studies only focused on one of these two variables. The comparison yields insights into the cyclicity of labor productivity.

Second, the chapter clarifies earlier studies by focusing on the size of the informal economy in absolute terms, rather than merely relative to the formal economy. Several earlier studies rested on examining the size of the informal economy relative to that of the formal economy, without explaining the underlying mechanism. For instance, when this ratio rises during recessions, it could reflect an expanding informal economy or an informal economy that shrinks less than the formal economy. Some previous studies have interpreted the rising ratio only as evidence for an expanding informal economy during recessions. The few previous studies of the procyclicality of informal output levels have been restricted to a small group of countries and either study solely output (Bajada 2003; Dell’Anno 2008; Giles 1997) or only employment (Fiess, Fugazza, and Maloney 2010).

Third, the chapter is the first to document a causal link from formal-economy developments to the informal economy by using an instrumental variables approach. This improves on existing studies that have tested for Granger causality between formal and informal economy within individual countries. The previous Granger causality tests help to determine whether one time-series is useful in forecasting another. However, they do not test for “true causality” (as instrumental-variable regressions do; Angrist and Pischke 2009), since omitted variables can generate spurious causality (Eichler 2009).

Main findings. The chapter reports two major results. *First*, informal-economy output moves in step with formal-economy output: informal-economy output movements are strongly positively correlated with formal-economy output movements. Hence, when earlier studies found that the share of the informal economy rose during formal-economy recessions, this reflected a slower absolute decline in informal than formal output rather than an absolute increase in informal activity (figure 1.3). In addition, this study finds that informal employment largely behaves “acyclically.”

Second, in an instrumental variable estimation, this study shows that the direction of causality runs from the formal economy to the informal economy. Specifically, it documents a causal link from fluctuations in formal-economy output to fluctuations in informal-economy output. In terms of employment, such a causal link is not found: whereas informal output behaves procyclically, informal employment is not cyclical. The latter may indicate that informal labor markets do not adjust in terms of

FIGURE 1.3 Formal and informal economy business cycles in EMDEs

The shares of informal output and employment rise significantly above their long-term averages during downturns in the formal economy. Informal output levels fall less than formal output levels; informal employment remains broadly stable while formal employment falls. The reverse holds for formal economic upturns.

A. Informal shares of output and employment

B. Changes in shares of informal economy during formal economy upturns and downturns

C. Output growth during formal economy upturns and downturns

D. Employment growth during formal economy upturns and downturns

Sources: Penn World Table 9.1; World Bank.

Note: Data are for 1990–2018. AEs = advanced economies; DGE = dynamic general equilibrium model estimates; EMDEs = emerging market and developing economies; FEMP = formal employment; LICs = low-income countries; MIMIC = multiple indicators and multiple causes model estimates; SEMP = self-employment. “Downturn” refers to growth rates of official GDP below zero, while “upturn” refers to growth rates of official GDP equal to or above zero. In B–D, *** indicates that the group average is significantly different from zero at the 10 percent level.

A. Bars show unweighted group averages for the latest year available, with the whiskers showing ± 1 standard deviation.

B. Shares of informal output (in percent of official GDP) and informal employment (in percent of total employment) are first-differenced and demeaned to capture detrended annual changes. Bars show unweighted group averages of detrended annual changes in shares of informal output/informal employment. Results for DGE-based estimates are shown in tenths (not percentage points).

C,D. Levels of output and employment in both formal and informal economies are logged, first-differenced and demeaned to capture detrended annual growth rates. Bars show unweighted group averages of detrended annual growth rates.

employment status during economic cycles but in terms of wages or working hours (Guriev, Speciale, and Tuccio 2019; Meghir, Narita, and Robin 2015).

Part II: Country and regional dimensions

Part II examines the features of informality across different economies and EMDE regions. Chapter 4 documents countries’ economic and social characteristics that are associated with higher informality. Chapter 5 documents differences and similarities across EMDE regions.

Chapter 4. Lagging Behind: Informality and Development

Widespread informality is associated with a plethora of development challenges, as shown in Chapter 4. Informal activity is widespread in emerging market and developing economies (EMDEs). While informality is often considered a cause of development challenges, it is also a consequence of under-development.⁹ EMDEs with more pervasive informality tend to be less developed; rely more on labor-intensive activities that employ unskilled and poorly paid workers; and have limited fiscal resources (World Bank 2019). Life expectancy, maternal mortality and other human-development indicators are, on average, lagging behind in EMDEs with more pervasive informality. Access to public services, such as electricity provision, that are essential to economic development, is limited.

A large informal sector weakens policy effectiveness and the government's ability to generate fiscal revenues.¹⁰ Government revenues in EMDEs with above-median informality are 5-12 percentage points of GDP below those with below-median informality (chapter 6). Limited fiscal resources constrain governments' ability to offer adequate coverage of social protection programs, provide broad access to public sector services, smooth business cycles, and close the productivity gap between the formal and informal sectors (Schneider, Buehn, and Montenegro 2010; World Bank 2020a). In turn, the limited access to public services further discourages firms and workers from engaging with the government, resulting in more participation in the informal sector (Loayza 2018; Perry et al. 2007).

EMDEs with widespread informality score particularly poorly on indicators of development. Many development outcomes are captured and quantified in measures of progress toward the Sustainable Development Goals (SDGs). In 2020, EMDEs with above-median informality, on average, ranked around 110 out of 166 in overall SDG achievement, which is significantly worse than EMDEs with below-median informality (figure 1.4). About one-quarter (26 percent) of the population of EMDEs with above-median informality lived in extreme poverty, much more than the 7 percent of the population in the EMDEs with below-median informality. In countries with greater informality, income inequality was higher, in part reflecting the wage gap between formal and informal workers and less progressive tax policies (Chong and Gradstein 2007; World Bank 2019; box 4.1).

Against this backdrop, this chapter addresses the following questions:

- What are the development challenges associated with the informal economy?
- What are the correlates of widespread informality?
- What are the correlates of changes in the informal sector over time?

⁹ See Fields (1975); Harris and Todaro (1970); Loayza (2016); and Ulyssea (2020).

FIGURE 1.4 Development challenges and informality

EMDEs with widespread informality face a host of development challenges, ranging from extreme poverty to lack of public infrastructure. Those with more pervasive informality lag behind in Sustainable Development Goals (SDGs).

A. SDG Global Index Rank

B. Extreme poverty headcount

C. Wage premium for formal over informal employment

D. Differences in fiscal indicators between EMDEs with above-median and below-median output informality

E. Quality of infrastructure

F. Probability of inclusion of variable group among explanatory variables of informality

Sources: Sachs et al (2018); Sachs et al. (2020); World Bank (World Development Indicators).

Note: EMDEs = emerging market and developing economies; DGE = dynamic general equilibrium model-based estimates in percent of official GDP. "High informality" ("Low informality") are EMDEs with above-median (below-median) DGE-based informal output measure over the period 1990-2018 (unless otherwise specified). *** indicates that group differences are significant at the 10 percent level.

A. Simple averages for 2020 for 132 EMDEs. A higher SDG global index rank indicates greater achievement of SDGs. Informality as measured by share of DGE output informality in GDP.

B. Simple averages for 155 EMDEs with "high informality" or "low informality." "Latest" refers to data from latest year available (2018 or earlier). Poverty headcount ratio is the percent of the population living on less than \$1.90 a day at 2011 international prices.

C. The wage premium (shown in bars) is obtained from 18 empirical studies on the wage gap between formal and informal workers. The whiskers show the 90 percent confidence intervals. See box 4.1 for details.

D. Differences in percentage points of GDP between the average fiscal indicators among EMDEs with above-median and below-median informality are in bars. The whiskers show the 90 percent confidence intervals. All fiscal indicators and informality measures are 2000-18 averages for 74 EMDEs with populations above 3.5 million. (Several oil-exporting economies are dropped as outliers.)

E. Simple averages for the latest year available (Sachs et al. 2018).

F. Probability of including at least one variable from the group in the regression (posterior inclusion probability). The groups whose posterior inclusion probabilities exceeded the prior of 50 percent (horizontal bar) can be regarded as most relevant.

Contributions. The chapter makes the following contributions to the literature on informality. *First*, it provides a systematic and comprehensive overview of developmental challenges facing countries with large informal sectors, highlighting their association with a wide range of development weaknesses and shortfalls from the SDGs. Previous studies have focused on the economic or institutional correlates of informality—such as per capita income (for instance, La Porta and Shleifer 2014; Loayza, Servén, and Sugawara 2010) or control of corruption (for instance, Choi and Thum 2005; Dreher and Schneider 2010)—and largely disregarded the linkages between informality and other aspects of sustainable development, ranging from life expectancy to lack of access to public infrastructure.

Second, the chapter is the first published study to empirically and systematically document a broad range of correlates of informality in a large group of EMDEs, numbering about 130 countries. Previous studies have tended to focus on one dimension of informality, rely on a more limited range of correlates, or only examine the correlates of cross-country differences in informality without focusing on EMDEs.¹¹ To identify the robust correlates of informality, the chapter is also the first to use a Bayesian Model Averaging (BMA) approach, which is designed to take account of model uncertainty (Fernandez, Ley, and Steel 2001).

Third, this chapter illustrates how informality can pose development challenges in EMDEs. First, it conducts the first extensive meta-analysis of studies that documented wage differences for workers in formal and informal sectors. Second, it utilizes a unique firm-level dataset to show how the productivity gap between formal and informal firms in EMDEs can be narrowed by improvements in business climates.¹² Third, it empirically tests for the robustness of the relationship between declines in informality and poverty reduction (or income inequality).

Main findings. The chapter demonstrates that EMDEs with pervasive informality face a wide range of greater development challenges than other EMDEs. *First*, informality is associated with poor economic outcomes. Countries with larger informal sectors have lower per capita incomes, greater poverty, less financial development, and weaker growth in output, investment and productivity. Informal firms are less productive than their formal counterparts (box 4.2).

Second, more pervasive informality is associated with significantly lower government revenues and expenditures, less effective policy institutions, more burdensome tax and regulatory regimes, and weaker governance. Weaknesses in governance and revenue collection constrain the provision of public services in EMDEs with more pervasive informality, contributing to poorer human development outcomes. People living in EMDEs with more widespread informality suffer from a greater prevalence of hunger,

¹¹ For instance, Medina and Schneider (2019); Ovedio, Thomas, and Karakurum-Özdemir (2009); and Schneider, Buehn, and Montenegro (2010).

¹² Existing studies, such as Meghir, Narita, and Robin (2015) and Ulyssea (2018), show the productivity gap between formal and informal firms in individual countries.

poorer health and education, and greater gender inequality. Countries with more widespread informality offer poorer access to, and lower-quality, infrastructure.

Third, the results from the BMA approach suggest that economic development, human capital, and governance are particularly robust correlates of output informality. That said, other correlates such as infrastructure, for instance, are also relevant.

Fourth, while informality is linked with a host of developmental challenges, formalization alone is unlikely to offer an effective path out of under-development. For instance, while declines in informality were associated with poverty reduction, they were not systematically linked with declining income inequality (box 4.3). This may reflect the fact that informality itself is a symptom of underdevelopment, in line with the meta-analysis of the literature that finds that the wage penalty largely reflects the characteristics of informal workers (box 4.1).

Chapter 5. Informality in Emerging Market and Developing Economics: Regional Dimensions

Chapter 5 explores regional differences in informal activity in EMDE regions and their implications for policies. Before the COVID-19 pandemic, informality was falling in the average EMDE over two decades, although the pace of decline varied widely across EMDE regions. The correlates of informality also vary across regions, shaped by distinctive regional cultures and histories, as well as economic, social and policy structures.

This chapter addresses the following questions:

- How has informality evolved over the past two decades in each EMDE region?
- What are the correlates of informality in each region?
- What policy options are available to address the challenges associated with informality in each region?

Contributions. The chapter makes the following contributions to the literature. *First*, the chapter brings a regional perspective to the existing literature on informality in EMDEs. Past studies either grouped all countries together or focused on one or a few countries or a specific region. The chapter distills commonalities among EMDEs within each region and differences across regions. *Second*, the chapter brings together multiple strands of literature by investigating two key types of informality—output and employment informality—thus helping policy makers better understand the nature of informality in their respective regions. Previous studies typically examined either output informality or employment informality. Lastly, the chapter provides policy recommendations that are tailored to regional specific needs and conditions. Former studies tend to have a broad overview of all relevant policies without applying them to regional context.

Main findings. *First*, the chapter documents large differences in the evolution of informality across regions. Output informality is highest in ECA, LAC, and SSA, while employment informality is highest in EAP, SAR, and SSA (figure 1.5). Output informality declined most in EAP and SAR between the 1990s and the 2010s, while employment informality fell most in MNA, SAR, and SSA. Despite declines in output informality, and consistent with slower productivity growth in the informal than the formal sector, employment informality remained broadly unchanged in EAP, ECA, and LAC between 1990-99 and 2010-18.

Second, a mix of cross-regional, intra-regional, and country-specific factors are associated with informality in EMDEs. Key correlates of high informality include low human capital, large agricultural sectors, and poor business climates. But there are also important region-specific factors, such as insufficient social protection coverage, trade liberalization, and economic disruptions due to armed conflict. Reflecting regional as well as national differences in informality, balanced policy mixes tailored to country circumstances are required to set the right conditions for informality to fall.

Part III: Policies

Part III examines the policy options available to address the challenges posed by informality. In particular, Chapter 6 offers a menu of policy options to address both long-term and short-term challenges and flags unintended consequences experienced in past policy experiments.

Chapter 6: Tackling Informality: Policy Options

Chapter 6 documents the challenges that informality poses for macroeconomic policies and explore policy options to address these challenges. Over the past three decades, many EMDE governments have implemented a wide range of policy reforms that may have helped to reduce informality (Jessen and Kluge 2021). These reforms have often been implemented to either increase the benefits of formal-sector participation or reduce the costs of formal activity.

Both corporate and personal income tax rates in EMDEs have been reduced by about one-third between the early 1990s and 2019 (Végh and Vuletin 2015). Time spent on paying taxes was also cut by about one-third in EMDEs between 2006 and 2020. Value-added taxes, which can lower tax burdens through a refund on input taxes, had been adopted in 71 EMDEs by 2020 (World Bank 2020b). Access to financial services has broadened, with access to automatic teller machines (ATMs) per 100,000 adults and the share of the population with an account at a financial institution both increasing by more than 50 percent between 2010 and 2018. Over the same period, one-third to two-thirds of EMDEs improved their governance and institutional quality.

Policy reforms often had more benign effects on informality when they were implemented in a supportive institutional and macroeconomic environment. For instance, trade liberalization programs were often associated with greater informality in

FIGURE 1.5 Informality in EMDE regions

Informality is pervasive across all EMDE regions. Although the share of informal output in GDP has fallen over time, its incidence remains high in the regions with the lowest per capita incomes.

A. EMDE regions' shares of world output and employment

B. Output and employment informality by region

C. Output informality by region

D. Employment informality by region

E. GDP per capita and output informality

F. GDP per capita and employment informality

Sources: International Labour Organization; World Bank.

Note: Output informality is proxied by the estimates using a dynamic general equilibrium (DGE) model in percent of official GDP. Employment informality is the share of self-employment in total employment. EAP = East Asia and Pacific; ECA = Europe and Central Asia; LAC = Latin America and the Caribbean; MNA = Middle East and North Africa; PPP = purchasing power parity; SAR = South Asia; SSA = Sub-Saharan Africa.

A. DGE-based estimates of informal output in each region as a proportion of total estimated informal GDP. Estimates are based on economies' shares of output and employment averaged over the period 2010-18.

B. Blue bars show the simple average share of informal output as estimated by DGE model during 2010-18. Red bars show the simple average informal employment rate (proxied by self-employment rate) during 2010-18.

C.D. Bars are simple averages for corresponding regions and time periods.

E.F. Grey markers show unweighted average log GDP (2011 PPP \$) relative to informal output and employment, with the fitted line shown in blue and the corresponding +1 and -1 standard errors shown in shaded gray areas. Red markers show median GDP per capita and median informal output (E) and employment (F) in EMDE regions. Data are for 2010-18.

the short term—unless they were accompanied by greater labor market flexibility and an upgrading of skills in the labor force (Goldberg and Pavcnik 2003; McCaig and Pavcnik 2015; World Bank 2019).

The untapped potential of informal sectors, if harnessed to boost income growth and resilience, can help build back better from the severe global recession of 2020. Against this background, the chapter addresses the following questions:

- Which fiscal measures can help reduce informality?
- Which other policies can help reduce informality?
- What should be the elements of a comprehensive policy package to tackle informality?

Contributions. The chapter makes the following contributions to the literature. *First*, it offers a systematic review of policies that could affect informality, ranging from fiscal policies to labor market regulations and policies to encourage financial development. It covers both policies that are intentionally designed to encourage formalization and ones that could incidentally affect the informal sector.

Second, the chapter is the first attempt to comprehensively examine the link between financial development and informality both theoretically and empirically (box 6.1). It reviews the literature identifying the channels through which limited financial development can discourage formalization. It uses both descriptive statistics and regression approaches to show that informality is associated with lack of financial development, and that improvements in access to finance are associated with declining informality.

Third, the chapter describes novel empirical estimates of the cumulative changes in informality following various policy changes, obtained using a local projection model. Policy-related variables examined include tax rates, access to credit by the private sector, labor market efficiency, governance, and regulatory quality. This is the first study to conduct such empirical analysis for a wide range of policies. It is also the first to examine the share of informality in both economic output and employment: earlier studies have tended to focus on either informal output, or informal employment, or informal firms.¹³

Main findings. *First*, macroeconomic policies, governance and business climates have become more conducive to lowering informality over the past three decades. In the past three decades, EMDEs have made progress in reducing tax burdens, improving governance and regulatory quality, and enhancing access to finance, education, and public services (figure 1.6).

FIGURE 1.6 Policies to address challenges of informality

Governments have implemented a wide range of reforms that could affect informality.

A. Reforms in advanced economies and EMDEs

B. Reforms across EMDE regions

C. Reforms over time

D. Reforms over time (continued)

E. Economies with improvement in control of corruption

F. Economies with improvement in the ease of doing business

Sources: *International Country Risk Guide*; World Bank (*Doing Business*).

Note: See *Doing Business* database for reform details. EAP = East Asia and Pacific; ECA = Europe and Central Asia; EMDEs = emerging market and developing economies; LAC = Latin America and the Caribbean; MNA = Middle East and North Africa; SAR = South Asia; SSA = Sub-Saharan Africa.

A.B. The number of policy reforms for an average country over the period 2008-18 that are regarded as "improvements" (according to components of the ease of doing business index) or "neutral" (with regard to "labor market regulation").

C.D. For an average country, the average number of policy reforms per year that have been implemented during 2008-10 in comparison to the annual average number of reforms conducted during 2016-18 (shown in bars).

E.F. Bars show the shares of economies with improved control of corruption (E; the ease of doing business in F) between 2010 and 2018.

Second, policies that seek to streamline tax regulation, strengthen tax administration, and improve public service delivery have been associated with declines in informality. Separately, policies aimed at invigorating private sector activity broadly, such as measures to increase labor market flexibility, streamline regulatory frameworks for firm start-up, expand access to finance, and improve governance have also been associated with declines in informality.

Third, policy measures can have unintended consequences. For instance, trade liberalization that raised competition in the tradable sector was sometimes associated with greater informality in the short run, unless accompanied by measures that increase labor market flexibility. Also, reductions in informality have tended to be greater for reforms accompanied by business development and training programs, public awareness campaigns, and stronger enforcement.

Fourth, financial development has been associated with declining informality (box 6.1). It reduces the average costs of access to external financing and incentivizes firms to invest in higher-productivity projects and to join the formal sector. Over the past three decades, increased access to financial services and increased credit availability have been followed by declining informality.

Fifth, a comprehensive policy package tailored to country circumstances offers the greatest chance of success in reducing informality. A combination of measures to strengthen economic development, boost productivity in both formal and informal sectors, streamline regulations and ensure effective enforcement can address multiple sources of informality. The relative priorities will depend on the country-specific features of informality.

Future research directions

The study suggests several avenues for future research.

Concepts and measurement. Despite the richness of the informality database compiled in chapter 2, the limitations and weaknesses of existing measures remain. Future research could improve the quality of these measures and explore new approaches to better capture the extent of informality in EMDEs. Chapter 2 distills the main features of informal economy business cycles but does not look into the factors and policies that could trigger cyclical turning points. Further analysis in this direction would be valuable.

Cyclical behavior of the informal economy. Chapter 3 focuses on how informal output and employment behave over the business cycle and points to several promising areas for future research. First, the cyclical behavior of other features of the informal economy could be examined. For example, if greater flexibility of wages or hours worked is indeed what makes informal employment acyclical despite procyclical informal output, informal wages or hours should be particularly procyclical, and evidence of this would be useful. Second, the channels through which formal-economy business cycles affect the informal economy could be further explored and quantified. This includes the

degree of interconnectedness between formal and informal firms. Third, the impact of the pandemic on the informal sector and the effectiveness of policy responses should be studied further.

Consequences of informality for development. Chapter 4 establishes the linkage between informality and a range of symptoms of underdevelopment. However, it does not demonstrate a causal link between informality and various development outcomes. Future research could aim to uncover, for at least some of these correlates, the degree to which informality *causes* underdevelopment. Second, due to data limitations, some variables, such as access to paved roads and bank account ownership, that are relevant to informality are not included in the empirical analysis. Future studies can improve upon the work reported here by incorporating those variables. Third, future research could explore asymmetries in the challenges posed by informality. There may be interactions between country circumstances and worker or firm characteristics that can mitigate some of the challenges posed by informality. For firms, some of these interactions were explored in box 4.2 but other important interactions may yet come to light in future research.

Regional perspectives of informality. The varied nature of informality in EMDEs requires different policy mixes appropriate to each country's circumstances. Drawing on the discussion of policy options for different regions in chapter 5, future research could look into options that could be considered for implementation at a regional level. This could, in particular, include an examination of promising new areas such as digitalization.

Policy options. A few policy areas remain under-explored in the literature. First, while digitalization is a recent development, it holds great potential for both informal-economy participants and policy makers. Chapter 6 does not touch upon the practical perspectives of realizing the potential of digitalization in EMDEs with pervasive informality, and this could be an area for future research. Little is known about the impact of digitalization of government services or private economic activity on the informal economy. Second, past studies have focused on the impact of policies on formalization without looking into their effects on vulnerable groups active in the informal economy. Future studies could examine policies that can better protect these groups and prevent informal participants from being tipped into poverty by negative shocks such as COVID-19.

PART I

Characteristics of the Informal Economy

CHAPTER 2

Understanding the Informal Economy: Concepts and Trends

By its nature, informal economic activity—referred to in this study simply as “informality”—is difficult to observe systematically and to measure. This chapter introduces a comprehensive database of informality measures. This database shows that informality remains pervasive in emerging market and developing economies (EMDEs), notwithstanding a declining trend over the past three decades. Like the formal economy, the informal economy undergoes business cycles, which resemble those in the formal economy. Informal-economy output fluctuations tend to be more pronounced in EMDEs than in advanced economies, whereas employment fluctuations are more limited and do not differ significantly between the two groups.

Introduction

The livelihoods of the poor in emerging market and developing economies (EMDEs) often depend on informal economic activity. In these economies, informal-economy output on average accounts for about one-third of GDP and informal employment constitutes about 70 percent of total employment (of which self-employment accounts for more than one-half; figure 2.1). In some economies in Sub-Saharan Africa (SSA), informal employment accounts for more than 90 percent of total employment and informal output for as much as 62 percent of official GDP (ILO 2018a).

Depending on country circumstances and worker characteristics, workers may choose informal employment for a wide range of reasons. Thus informal workers range from agricultural day laborers to self-employed firm owners with a few employees.

A large informal sector has tended to be associated with unfavorable macroeconomic and development outcomes (figure 2.1; chapter 4). On average, economies with larger informal sectors have tended to have less access to finance for the private sector, lower productivity, slower physical and human capital accumulation, less educated workforces, and smaller fiscal resources (Docquier, Müller, and Naval 2017; La Porta and Shleifer 2014; World Bank 2019a). Some studies show that informality is associated with higher income inequality and poverty (Chong and Gradstein 2007; Loayza, Servén, and Sugawara 2010; Perry et al. 2007; Rosser, Rosser, and Ahmed 2000). Lower physical investment in the informal sector could reflect an unwillingness of informal firms to adopt technologies or larger scales of production that might make them visible to tax and other authorities (Dabla-Norris, Gradstein, and Inchauste 2008; Gandelman and

Note: This chapter was prepared by Ceyhan Elgin, M. Ayhan Kose, Franziska Ohnsorge, and Shu Yu. Research assistance was provided by Zhuo Chen, Lorez Qehaja, and Xinyue Wang.

FIGURE 2.1 Informality: Magnitude, variety, and development challenges

The informal sector accounts for about a third of GDP and more than 70 percent of employment (of which self-employment accounts for more than one-half) in emerging market and developing economies (EMDEs). A large informal sector is often associated with lack of development and weak governance as well as greater poverty and income inequality. In some cases, informal workers voluntarily choose informal activity.

A. Shares of informal output and self-employment

B. Informality: Output, employment, and perception

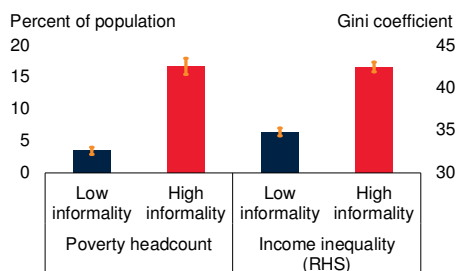

C. Informal output and development

D. Brazil: Share of informal workers preferring informal over formal employment

E. Informality, poverty, and income inequality

F. Governance in EMDEs, by informality

Sources: *International Country Risk Guide* (ICRG); International Labour Organization; Maloney (2004); World Bank (World Development Indicators, WDI; World Governance Indicators, WGI); World Economic Forum; World Values Survey (WVS).
 Note: "High informality" ("Low informality") indicates economies with above- (below-) median informal output (using DGE-based estimates). DGE = dynamic general equilibrium model-based estimates of informal output in percent of official GDP; EMDEs = emerging market and developing economies; MIMIC = multiple indicators multiple causes model-based estimates of informal output in percent of GDP; WEF = World Economic Forum estimates; WVS = World Values Survey estimates.
 A. Unweighted averages. Informal employment uses self-employment shares (in percent of total employment). Missing values are interpolated or filled using the latest available observations. World averages between 1990-2018 are in orange.
 B. Unweighted averages for latest available year. Whiskers are +/-1 standard deviation. Measures are grouped into output informality, employment informality, and perception-based informality. Data on informal employment are for EMDEs. See table 2.1.A for details.
 C. Latest available year (2018). Orange line shows fitted values. "Ln (GDP per capita)" is the logarithm of GDP per capita (in constant 2010 U.S. dollars).
 D. The share of informal workers preferring informal over formal employment (Maloney 2004).
 E. Data are for 1990-2018. Group means (bars) and 90 percent confidence intervals (whiskers) are shown for poverty headcount ratio (percent of population living on \$1.90 a day at 2011 PPP) and Gini coefficients.
 F. Data for 1990-2018 and EMDEs. Bars show unweighted averages of ICRG data; whiskers show 90 percent confidence intervals.

Rasteletti 2017). The informal sector, on average, is characterized by lower productivity than the formal sector because it tends to employ less-skilled workers; use less capital; have restricted access to funding, services and markets; and lack economies of scale (Amaral and Quintin 2006; Galiani and Weinschelbaum 2012; Loayza 2018). These long-term economic correlates of informality are explored in chapter 4.

Over the business cycle, informal employment can provide a safety net when the formal sector sheds jobs (Loayza and Rigolini 2011). But workers in the informal economy are largely excluded from the social security system and less protected against negative shocks than workers in the formal sector, which could amplify business cycles (box 2.1; chapter 3).

Against this backdrop, this chapter reviews conceptual and measurement issues regarding the informal economy and documents its main features across countries and over time. Specifically, it addresses the following questions:

- How is the informal economy defined?
- How has informality evolved?
- What are the features of the informal economy?

The chapter makes the following contributions to the literature. First, it compiles a comprehensive database of informality measures developed in the literature, with a focus on measures that have broad cross-country and long historical coverage. The resulting dataset combines 12 cross-country databases and data provided by almost 90 national statistical agencies.¹ Second, the chapter presents two applications of this database. In a first step, it distills stylized facts about the informal economy, such as its size and evolution over time, using a wide range of informality measures, and tests the consistency of these stylized facts across these measures. In a second step, the chapter documents the cyclical features of the informal economy, such as the duration and amplitude of its recessions and recoveries.

The chapter presents several new findings. First, the chapter summarizes the advantages and drawbacks of existing informality measures. Most of the macroeconomic literature on informality has relied solely on either survey-based or model-based estimates. Survey-based measures can cover many dimensions of the informal economy, but they suffer from poor country and year coverage (especially for EMDEs), reporting bias, and lack of consistency in survey methods.² Indirect, model-based measures of informal output

¹ Official GDP statistics often make an adjustment for informal activity. However, the magnitude of such adjustments is rarely specified. In a survey in 2008, national statistical agencies for about 40 mostly advanced economies or economies in transition reported adjusting their official GDP statistics by amounts ranging from 0.8 to 31.6 percent for activity in the non-observed economy (NOE), which is a broader concept than the informal economy (United Nations 2008). For all reporting economies, the adjustments were well below those suggested by the measures of informality presented in this chapter.

² Survey-based informality measures are based on income data from surveys or audits that differ from incomes declared for tax purposes (Binelli and Attanasio 2010; McCaig and Pavcnik 2015), or earnings from firm surveys (Almeida and Carneiro 2012; Putnins and Sauka 2015).

BOX 2.1 How does informality aggravate the impact of COVID-19?

COVID-19 has taken an especially heavy humanitarian and economic toll on emerging market and developing economies (EMDEs) with large informal sectors. Large informal sectors make lockdowns and social distancing particularly challenging, thus reducing governments' ability to stem the spread of the virus. Informal workers tend to be employed in activities and locations where social distancing is difficult to implement. With few savings and lack of access to formal social benefits, many struggle to comply with government lockdown orders. Economies with large informal sectors are also associated with weak health care systems that can result in a larger number of fatal outcomes of infections. These vulnerabilities amplify the economic shock to livelihoods from COVID-19 and threaten to raise global extreme poverty. It is therefore critical to implement effective delivery channels for support to informal workers and firms. Unconditional support programs may be appropriate. Given their limited resources, low-income countries may require increased international funding for the effective implementation of such programs.

Informal activity is widespread in emerging market and developing economies (EMDEs; figure B2.1.1; World Bank 2019a). Large informal sectors are often associated with underdevelopment, with activity typically characterized by labor-intensive production, less educated and more poorly paid workers, limited access to financial and medical service, and poor or non-existent coverage by social security. These features are likely to intensify the spread of COVID-19 among informal workers and worsen its adverse health and economic impacts (Nguimkeu and Okou 2020). Starting from a relatively lower level, confirmed COVID-19 cases have been rising rapidly in EMDEs with extensive informality since the end of March 2020, despite a lower level of testing.

Against this background, this box addresses the following questions.

- Which features of the informal economy can amplify or dampen the impact of the pandemic?
- How may widespread informality alter the impact of the pandemic?
- How do policies to mitigate the impact of the pandemic need to be tailored to the presence of large informal sectors?

Features of the informal economy

The informal economy has several features that tends to facilitate the spread of the pandemic. Other features worsen the economic impact of adverse shocks more generally.

Note: This box was prepared by Shu Yu.

BOX 2.1 How does informality aggravate the impact of COVID-19? (continued)

FIGURE B2.1.1 Informality in EMDEs

Informality is particularly prevalent in emerging market and developing economies (EMDEs). In Sub-Saharan Africa, Europe and Central Asia, and Latin America and the Caribbean, informal output averaged about 35 percent of GDP in 2010-18. Self-employment in Sub-Saharan Africa, South Asia, and East Asia and the Pacific, ranged from about 50 percent of employment to more than 60 percent. Confirmed COVID-19 cases have grown rapidly since the end of March 2020 in EMDEs, with some concern about lack of testing in EMDEs with above-median informality.

A. Informality in EMDEs

B. Informality across EMDE regions

C. COVID-19 cases and the extent of informality

D. Informality and COVID-19 tests

Sources: Haver Analytics; International Monetary Fund (Government Finance Statistics); *Our World in Data*; World Bank (World Development Indicators).

Note: EAP = East Asia Pacific, ECA = Europe and Central Asia, MNA = Middle East and North Africa, SAR = South Asia, SSA = Sub-Saharan Africa. In C-D, informality is measured by DGE-based informal output in percent of official GDP in 2018. DGE = dynamic general equilibrium model-based estimates of informal output in percent of official GDP; EMDEs = emerging market and developing economies.

A. Simple averages. Informal employment uses self-employment shares with missing value interpolated in EMDEs for earlier years and filled using the latest available observation in recent years. World averages between 1990 and 2018 are orange.

B. Simple averages of informal output (DGE-based estimates) and employment estimate (share of self-employment) in each region during 2010-18.

C. Bars show the total number of confirmed COVID-19 cases (in thousands or millions) for EMDEs (excluding China) with less informality (that is, above group median) and EMDEs (excluding China) with less informality (that is, below group median) on March 24, 2020, and on February 12, 2021 (RHS).

D. Bars show the simple average number of COVID-19 tests per 1,000 people for EMDEs (excluding China) with less informality (that is, above group median) and EMDEs (excluding China) with less informality (that is, below group median) on February 12, 2021. The left two bars show the total number of COVID-19 tests done so far, and the right two bars show the daily number of COVID-19 tests performed. *** indicates that group averages are significantly different at 10 percent level.

**BOX 2.1 How does informality aggravate the impact of COVID-19?
(continued)**

Widespread informality in EMDEs. The informal sector, on average, accounts for about a third of official GDP and about 70 percent of total employment in EMDEs (of which self-employment accounts for more than one-half; figure B2.1.1; World Bank 2019a). Informal enterprises account for 8 out of every 10 enterprises in the world (ILO 2020a). The size of the informal economy varies widely across regions and countries. The share of informal output is highest in Sub-Saharan Africa (SSA), Europe and Central Asia (ECA), and Latin America and the Caribbean (LAC), averaging near 40 percent of GDP in those regions between 2010 and 2018. The share of self-employment, another measure of informality, is highest in SSA, South Asia (SAR), and East Asia and the Pacific (EAP), ranging from 50 percent to 62 percent of total employment. In 2018, the informal economy accounted for more than 50 percent of GDP in Bolivia and Zimbabwe.^a The sector accounted for about 90 percent of total employment in Mali, Mozambique, and India. In economies like Kenya, 8 out of 10 workers were self-employed.^b

Characteristics of informal workers. Workers in the informal sector tend to be lower-skilled and lower-paid, with less access to finance and social safety nets than workers in the formal sector (Loayza 2018; Perry et al. 2007; World Bank 2019a). They often live and work in crowded conditions and conduct all transactions in cash—factors that facilitate the spread of disease (Chodorow-Reich et al. 2020; Surico and Galeotti 2020). Informal workers on average have incomes 19 percent lower than formal workers and have limited savings (figure B2.1.2; World Bank 2019a). In the one-third of EMDEs with the most pervasive informality, more than one third of the population would be driven into poverty if they had to cover direct out-of-pocket payments for an unexpected health care emergency. On average, unemployment benefits are only available to a small fraction of the population (less than 4 percent) in EMDEs with above-median output informality between 1990 and 2018.

Characteristics of informal firms. Informal firms tend to be characterized by labor-intensive production and are more prevalent in the services sector. These have been hard hit by measures to curtail social interactions (Benjamin and Mbaye 2012; Surico and Galeotti 2020). In EMDE service sectors, about 72

a. Here, DGE-based estimates are used to capture output in the informal sector. MIMIC-based estimates of informal output indicate that other economies also have informal output exceeding 50 percent of GDP.

b. Common employment measures of informality are ratios of *self-employment* and *informal employment* to total employment. The *self-employed* work on their own account, or with one or a few partners, or in a cooperative. *Informal employment* comprises all workers of the informal sector and informal workers outside the informal sector (World Bank 2019a).

BOX 2.1 How does informality aggravate the impact of COVID-19? (continued)

FIGURE B2.1.2 Features of the informal sector

Many informal workers are employed in the agricultural or services sectors, poorly paid, with limited access to social benefits, and at risk of impoverishing health spending.

A. Productivity in the informal sector

B. Agricultural sector

C. Risk of impoverishing expenditure for surgical care

D. Social insurance

E. Informality in manufacturing and services

F. Wage premium for formal over informal employment

Sources: Amin, Ohnsorge, and Okou (2019); Program in Global Surgery and Social Change (PGSSC) at Harvard Medical School; World Bank (Enterprise Surveys, World Development Indicators); World Bank.

Note: *** indicates the group differences are not zero at 10 percent significance level. DGE = dynamic general equilibrium model-based estimates of informal output in percent of official GDP.

A. Firm productivity is measured as sales per worker.

B.C. Bars are simple group mean for EMDEs. "High informality" are the highest one-third of EMDEs by DGE-based informal output and "low informality" are the lowest one-third over 2010-18.

D. Bars are simple group mean for EMDEs. "High informality" are the highest half of EMDEs by DGE-based informal output and "low informality" are the lowest half over 1990-2018. Adequacy of social insurance programs are measured in percent of total welfare of beneficiary households.

E. Data coverage as in Amin, Ohnsorge, and Okou (2019).

F. The wage premium is obtained from 18 empirical studies. See World Bank (2019a) for details. BRA = Brazil, CRI = Costa Rica, ECU = Ecuador, MEX = Mexico, MDG = Madagascar, PER = Peru, SLV = El Salvador, RUS = Russian Federation, TUR = Turkey, UKR = Ukraine, VNM = Vietnam, ZAF = South Africa. The number of studies or estimates for each country is shown in parenthesis; country means are calculated using a random-effects meta-analysis model.

BOX 2.1 How does informality aggravate the impact of COVID-19? (continued)

percent of firms are informal, compared with 33 percent in EMDE manufacturing sectors (see Amin, Ohnsorge, and Okou 2019 for sample coverage). Agricultural employment in EMDEs is roughly 90 percent informal. Epidemic-control measures have already disrupted access to markets and inputs and may also eventually threaten the food security of smallholder farmers (Cullen 2020; FAO 2020; ILO 2018b).

Broader development challenges. Economies with larger informal sectors are associated with weaker economic, fiscal, institutional, and developmental outcomes. GDP per capita in economies with above-median informality is about one-quarter that of economies below-median informality (Chapter 1). Health systems in EMDEs with more informality are relatively underdeveloped, and government capacity to mount an effective policy response to pandemics is limited.

- *Health and sanitation.* Although the populations of EMDEs with the most pervasive informality tend to be younger, they also tend to be less healthy, live in less sanitary conditions, and only have access to weak public health and medical systems (figure B2.1.3).^c In the one third of EMDEs with the most pervasive informality, sanitation facilities are accessible to only 36 percent of the population, and clean drinking water is available to only 54 percent of the population, compared to about 75 percent in the one third where informality is least pervasive. Hand-washing facilities are available for only 40 percent of the population in the former group. Access to medical care is also extremely limited in EMDEs with above-median informality, with only three-fourths the number of doctors and nurses per 1,000 people that the EMDEs with below-median informality have. In economies like Malawi and Kenya, thousands of people share access to only one or two ICU beds (Murthy, Leligdowicz, and Adhikari 2015).
- *Government policy effectiveness.* Economies with pervasive informality are less likely to have the institutional and fiscal capacity to mount an effective policy response to the pandemic. Tax avoidance is prevalent in the informal sector, resulting in limited fiscal resources (Besley and Persson 2014). For example, government revenues and expenditures in the EMDEs with the most pervasive informality are 5-10 percentage points of GDP, on average, below

c. In the one-third of EMDEs with the most pervasive informality, life expectancy at birth is 66.2 years, compared with 71.4 years in the one-third with the least pervasive informality. In the one-third of EMDEs with the most pervasive informality, the number of deaths per 1,000 people caused by communicable diseases and maternal, prenatal, and nutrition conditions are about twice as high as in the one-third with the least pervasive informality.

BOX 2.1 How does informality aggravate the impact of COVID-19? (continued)

FIGURE B2.1.3 Development challenges

Pervasive informality is associated with short life expectancy, lack of access to medical resources, limited sanitation facilities, and other health-system shortfalls. Economies with widespread informality have significantly lower government revenues and expenditures, substantially less effective governments, and greater corruption.

A. Life expectancy

B. Access to medical resources

C. Access to water, sanitation, and hygiene facilities

D. Mortality and disability adjusted life years

E. Government effectiveness

F. Fiscal indicators

Note: *** indicates statistically significant group differences at 10 percent significance. "High informality" are the highest one-third of EMDEs by DGE-based informal output and "low informality" are the lowest one-third over 2010-18.

A.C. Simple group means for EMDEs with "high informality" and those with "low informality" over 2010-18.

B. Simple group means for EMDEs over 2010-18. "Above-median informality" are EMDEs with above-median informality by the share of DGE-based informal output. Two outliers, Belize and Belarus, are dropped.

D. Simple group means for EMDEs with "high informality" and those with "low informality" over 2010-18 (2016 for DALYs). DALYs refers to disability adjusted life years -- the number of healthy life years per person lost to diseases. "COM" indicates years lost to communicable diseases and maternal, prenatal, and nutrition conditions.

E. Simple group means for EMDEs with "high informality" and those with "low informality" over 2010-2018. A higher value means better governance. "Bureaucracy quality" ranges from 0 to 4. The rest measures range from 0 to 6.

F. Simple average fiscal indicators for EMDEs with "high" informality and those with "low" informality over 2000-18. Sample includes 69 nonenergy-exporting EMDEs with populations above 3.5 million people.

BOX 2.1 How does informality aggravate the impact of COVID-19? (continued)

those with the least pervasive informality (World Bank 2019a; figure B2.1.3). In addition, governments are less effective, and corruption is more rampant, in economies with more pervasive informality (Loayza, Oviedo, and Servén 2006). Moreover, less than a quarter of informal firms use bank accounts and about one-half of small informal firms identified lack of access to finance as a major obstacle to their operations, which makes it difficult to use the financial system to channel support to the informal economy (Farazi 2014; Schneider, Buehn, and Montenegro 2010). The rising availability of digital payments—whether on mobile phones, cards, or online—provides an alternative financial channel for governments to reach the informal sector. However, it is doubtful whether sufficient cash-in and cash-out points are in place to allow people using digital payments to deposit and withdraw cash safely and reliably (World Bank 2017).^d The lack of registration also makes it a challenge to provide effective support to informal workers and firms via official fiscal measures (such as tax deductions).

Impact of the COVID-19 outbreak

As a result of these features of the informal sector, the impact of COVID-19 is likely to be worse in EMDEs with widespread informality. It can intensify the pandemic's adverse health and economic consequences while weakening the ameliorative effects of policies.

Health consequences. Health consequences of the pandemic are more adverse in EMDEs with more pervasive informality. In these countries, lack of adequate public health systems worsens the transmission of infectious disease. Access to clean water and handwashing facilities is often difficult or unfeasible. Living quarters and working environments are often overcrowded and insanitary. In SSA, where informality is pervasive, 70 percent of city dwellers live in crowded slums (World Bank 2019b). Lack of medical facilities and a generally less healthy population can worsen the severity of infections and limit the ability to treat those infected (Dahab et al. 2020). The absence of social safety nets means that informal market participants are unable to afford to stay at home, or to adhere to social distancing requirements, which undermines policy efforts to slow down the spread of COVID-19 (Loayza and Pennings 2020).

Economic consequences. Lockdowns hit informal market participants in the service sector, where informality is particularly common, especially hard (ILO 2020a; Panizza 2020). In SAR, about one of four households currently living in

d. These cash-in and cash-out points are often in the form of a bank agent, a mobile money agent, or an automated teller machine (ATM; Klapper and Singer 2017).

BOX 2.1 How does informality aggravate the impact of COVID-19? (continued)

poverty is engaged in informal activities in the service or construction sectors, which have been significantly affected by closures and disruptions (World Bank 2020a). Women are overrepresented in sectors that are subject to high risks during the pandemic: 42 per cent of women workers are in such sectors, compared to 32 per cent of men (ILO 2020a). Also, about 80 percent of informal firms rely on internal funds and financing from family and moneylenders for working capital, making them especially vulnerable to the disruption to cashflows caused by mitigation and other control measures (Farazi 2014). Informal workers too have limited financial resources to buffer temporary income losses during the containment period, making them more likely to be pushed into poverty.^e The health crisis also causes immediate revenue losses for firms, forcing them to temporarily or permanently close their businesses. This could trigger an unprecedented surge in unemployment and a potential expansion of the informal economy (ILO 2020b).

Past pandemics, such as the Ebola epidemic in West Africa in 2014-15, provide a stark illustration of the vulnerability of smallholder farmers (World Bank 2015).^f The agricultural sector has the highest share of informal employment—estimated at more than 90 percent (ILO 2018b). Farmers producing for the urban market may experience massive income losses as they are unable to sell their produce during the lockdowns (ILO 2020d).^g Small informal firms play a critical role in the food supply chain and are likely to run into operational distress and insolvency due to logistical breakdowns during containment periods (FAO 2020; ILO 2020b; World Bank 2020b). Since they are among the poorest and most vulnerable groups of society, informal workers, especially farmers, may have reduced access to food in the event of sharp income losses.

In countries with widespread informality, governments typically have neither the resources nor the administrative structures in place to effectively deliver well-targeted relief to those most in need (Muralidharan, Niehaus, and Sukhtankar 2016). In a number of EMDEs with widespread informality, social benefit

e. Without alternative income sources, lost labor income during the containment period could result in an increase in relative poverty for informal workers and their families of more than 21 percentage points in upper-middle-income countries and 56 points in lower and low-income countries (ILO 2020a). This could increase income inequality among workers (ILO 2020c).

f. In 2014-2016, the Ebola outbreak was followed by an economic crisis in West Africa, triggered by massive health and social spending to cope with the outbreak and compounded by the almost simultaneous collapse in commodity prices (Cangul, Sdravovich, and Sian 2017; World Bank 2014).

g. Farmers may be increasingly impacted by the health crisis if the virus spreads further into rural areas (ILO 2020a). In the case of India and Senegal, the inability of informal (or self-employed) workers to earn a living and gain access to health care has led to migration from urban to rural areas, which may cause the virus to spread further.

BOX 2.1 How does informality aggravate the impact of COVID-19? (continued)

systems, such as ration cards, are plagued by corruption that weakens their capacity to deliver support to the most vulnerable (Peisakhin and Pinto 2010; World Bank 2004).

Policy implications

Informality adds to the challenges of dealing with the Covid pandemic. Fiscal resources need to be used to strengthen public health systems to prevent, contain, and treat the virus, and to support the livelihoods of participants in the informal economy during the outbreak. As conventional measures—such as wage subsidies and tax relief—would hardly reach informal firms and workers, innovative emergency measures should be considered to deliver income support to informal workers, and credit support to informal firms (World Bank 2020b).^h When managing the tradeoff between coverage and costs, policy makers need to strive for a maximum reach to informal participants during the crisis, prioritizing temporary and reversible measures to minimize the longer-term fiscal burden. In some situations, however, the crisis has exposed gaps in a patchwork of social security facilities that should be filled, perhaps in the context of a thorough reform.

Expand social safety nets. The first line of response includes existing social protection and social assistance programs that could be quickly scaled up to provide immediate but temporary relief to families whose earnings have been adversely affected by the outbreak (World Bank 2020c, 2020d). Food aid, cash (or in-kind) transfers, and rent or utility bill waivers can be particularly effective in countries with pervasive informality, as they are easy to implement and have wide reach outside the formal sector (Özler 2020).ⁱ

Utilize flexible platforms and technologies to reach informal workers. Cash transfer and other support programs could utilize various existing registries and platforms that have wider coverage than banking or tax systems (Aker et al. 2016; Aron 2018). Such platforms should have sufficient coverage, provide possibilities to establish identities, and connect accounts with beneficiaries (World Bank 2020e). Examples include existing national social registries (for example, Brazil), new online platforms (Brazil and Thailand), new mobile payment devices

h. See World Bank (2020b) for details on the conventional measures. See ILO (2020b) for details on the importance of reducing the exposure of informal workers and their families to the virus and the risks of contagion and while ensuring their access to health care.

i. Where conditional programs exist, waiving conditionality for a period could ensure wider coverage in the context of a health emergency (World Bank 2020c). See World Bank (2020e) for a summary of country examples.

BOX 2.1 How does informality aggravate the impact of COVID-19? (continued)

(Morocco), and databases in health (Morocco) and energy (El Salvador) sectors. Public transfers via mobile money have been shown to improve food security and assets as compared to manual cash transfers in the short-term (Aker et al. 2016; Haushofer and Shapiro 2016).^j “Big data” analyses and geographic (or age-group or social group) targeting may help expand program coverage by identifying vulnerable groups that are not on any existing registry (Loayza and Pennings 2020; World Bank 2019a, 2020a, 2020e).

Facilitate access to finance for informal firms. To support informal firms, access to finance should be provided to help them stay in business, keep jobs, and maintain links to local and global value chains (World Bank 2020c, 2020f). Such support could be provided, potentially under government guarantees, by commercial banks, microfinance institutions, digital lending platforms, corporate supply chains, or other intermediaries. Easier access to credit, collateralization of existing properties, and online or mobile banking could help owners of informal firms to tap available financial resources, especially with the help of digital technologies.

Consider untargeted and unconditional programs when needed. Targeted programs reduce the risk that payments end up with those who do not need them, especially in the absence of effective targeting and delivery systems (Gentilini 2020; Loayza and Pennings 2020). In EMDEs where informality is pervasive and most of the population is either poor or near-poor, simple untargeted transfers may be better. Attempts to exclude the relatively few who are not in need would likely slow relief down and reduce the desired coverage of informal workers (Özler 2020). In practice, support programs that made formalization a condition of assistance have reduced the number of intended beneficiaries and have not offered net benefits to many informal enterprises (Campos, Goldstein, and McKenzie 2018). During the height of the pandemic and economic downturn, and the potentially weak recovery right afterwards, the need is to quickly reach as many informal workers and firms as possible. To this end, in many EMDEs, unconditional support programs would be advisable. Given their limited resources, low-income countries may require international funding for the effective implementation of such programs.

j. Mobile money is a technology that allows people to receive, store, and spend money using a mobile phone. Cash-in and cash-out points—a bank agent, a mobile money agent, or an automated teller machine—should be provided to ensure the success of public transfers via digital platforms (World Bank 2018).

stand out in their potentially comprehensive country and year coverage and their consistent economic meaning, but they rely on strong assumptions. The chapter highlights the circumstances in which the various individual informality measures could be particularly helpful. This adds to earlier work that has focused on the limitations of a confined number of estimation methods.

Second, the chapter argues that the combination of direct, survey-based indicators with indirect, model-based estimates can overcome the limitations of each. Informal employment measures tend to cover either the number of hours worked per day in informal employment (“intensity” of participation in informal employment) or, regardless of the number of hours worked per day, the presence of informal employment (“extent” of participation; Meghir, Narita, and Robin 2015). Since the extent of participation in the informal economy and its intensity may evolve differently, informal production may move asynchronously with informal employment.³ Thus measures of informal output are an important complement to measures of informal employment.

Third, the chapter distills the main features of the informal economy and its evolution over time. Three different dimensions of informality are identified in the chapter: output, employment, and perception. Cross-country rankings of informal output and employment are typically consistent. Both output and employment measures of informality have trended downward since 1990 and have shown some cyclicality. In contrast, perception-based measures have tended to be highly stable over time and could, therefore, be more appropriate for cross-country comparisons.

Fourth, the chapter describes the first study to document the cyclical features of the informal sector in both advanced economies and EMDEs. Cyclical movements in informal economy output do not differ statistically significantly from those in formal economy output. Like the formal economy, the informal economy undergoes larger output movements over the business cycle in EMDEs than in advanced economies. Steeper recessions and stronger recoveries in EMDEs contribute to greater output volatility, as shown in previous studies (Aguilar and Gopinath 2007). Meanwhile, unlike formal employment, which contracts significantly in advanced economies during formal economy recessions, informal employment in both advanced economies and EMDEs appears largely acyclical during informal output business cycles. This may reflect wage movements or changes in intensity (measured as number of hours worked per day) in labor markets, which may bear the brunt of adjustment during business cycles (Guriev, Speciale, and Tuccio 2019; Meghir, Narita, and Robin 2015).

The following section discusses how informality is defined and describes various measures of informality. Then, the chapter documents the main features of the informal economy across EMDE regions and the main similarities and differences across various

³For example, during a recession, labor may move from the formal sector to the informal sector and raise participation in the informal economy (Loayza and Rigolini 2011). However, due to the fall in demand during a recession, the intensity of participation, captured by the number of hours worked in informal employment, may remain the same or even drop, reducing informal output.

measures of informality. Next, it documents informal-economy business cycles, followed by concluding remarks.

Definition of informality

Informality is typically defined as market-based and legal production of goods and services that is hidden from public authorities for monetary, regulatory, or institutional reasons (Schneider, Buehn, and Montenegro 2010). Monetary reasons include the avoidance of taxes and social security contributions, regulatory reasons include the avoidance of government bureaucracy or regulatory burdens, and institutional reasons include corruption, related often to the poor quality of political institutions and weak rule of law. These factors affect firms and workers' decisions to participate in the formal sector (Perry et al. 2007; Ulyssea 2020). For the purposes of this book, the informal economy involves activities that, if recorded, would contribute to GDP, and does not cover illegal activities or household production (Medina and Schneider 2018; Schneider, Buehn, and Montenegro 2010). This section summarizes the definitions and classifications of informality used by previous studies.

Motivations for informal economic activity. The definition and classification of informality are highly context-specific. Similarly, the choice of informality measures will depend on the question being explored. The general definition referred to above encompasses many types of informal activities by workers and firms.

- *Exit versus exclusion.* Some workers and firms are “excluded” from the modern economy or from state benefit systems due to burdensome entry regulations and lack of human capital (de Soto 1989; Loayza, Oviedo, and Servén 2006; Perry et al. 2007). This type of informality is frequently associated with low productivity and with poorly paid and low-skilled employment (La Porta and Shleifer 2014; Loayza 2018). Other informal workers voluntarily “exit” the formal sector and choose informal activity for its flexibility, independence and lower regulatory compliance burdens (figure 2.1; Blanchflower, Oswald, and Stutzer 2001; Falco and Haywood 2016; Günther and Launov 2012; Maloney 2004). Both “excluded” and “exiting” types of informality could coexist in an economy (Bosch and Maloney 2008, 2010; Lehmann and Pignatti 2007; Nordman, Rakotomanana, and Roubaud 2016).
- *Subsistence informality.* Other studies focus on “subsistence informality,” which is pervasive in lower-income countries and characterized by low-skilled technology and the fact that in the absence of such informal economic activity the incomes of the workers involved would fall below subsistence levels (Docquier, Müller, and Naval 2017).
- *Evaders, avoiders and outsiders.* Yet another group of studies classify informal workers and firms into evaders, avoiders, and outsiders depending on their compliance with regulations and regulations' applicability (Kanbur 2009; Kanbur and Keen 2015). Evaders are firms that are covered by regulations but do not comply; avoiders are firms that adjust to be outside the remit of regulations; outsiders are firms that are simply not covered by regulations.

- *Margins.* More recent studies distinguish different types of informality by the entities engaged in informal activity, without focusing on their motivation: firms that do not register their business (the extensive margin) and or registered firms that hire workers “off the books” (the intensive margin; Ulysea 2018, 2020).

Informal workers. Informal employment covers all workers in the informal sector and informal workers outside the informal sector (Perry et al. 2007; ILO 2018a). The former comprises all persons who were employed in at least one informal firm. The latter group consists of some self-employed and workers who are not employed in formal contractual arrangements or not subject to social security or employment benefits.⁴ Some have defined informal employment more specifically as referring to workers who do not contribute to retirement pension schemes, which form part of social security (Loayza, Servén, and Sugawara 2010).

The most commonly used proxy for the relative size of informal employment is the share of self-employment in total employment, capturing workers who, working on their own account or with one or a few partners or in a cooperative, hold the type of jobs defined as “self-employment jobs” (annex 2A; ILO 1993; La Porta and Shleifer 2014). The other popular measure of informal employment comprises all workers in the informal sector (workers in at least one informal sector enterprise, irrespective of their status in employment and whether it was their main or a secondary job) together with informal workers outside the informal sector (the self-employed and employees holding informal jobs). For the remainder of the chapter, informal employment will be proxied by self-employment since data on informal employment is not available for advanced economies. The numbers throughout this chapter refer to the latest available years.

Informal firms. Some studies use the following criteria to define an informal firm (ILO 2018a). First, it is not an incorporated enterprise that is a legal entity separate from its owners, with its own complete set of accounts, and it is not owned or controlled by one person or a few household members. Second, it is a market enterprise that sells its goods or services. Third, it falls into one of the following categories: it keeps the number of workers employed on a continuous basis and below a threshold determined by the state; it is not registered; or its workers are not registered. Other studies provide an alternative definition of degrees of firm informality on a continuum depending on size, registration, honesty of accounting, tax payments, mobility of workplace and access to bank credit (Benjamin and Mbaye 2012; Mbaye, Benjamin, and Gueye 2017).

Database of informality measures

Reflecting the difficulty of measuring informality, researchers have developed a wide range of estimation methods to capture its scale. The database compiled for this study includes the twelve measures most commonly used in the literature. These can be

⁴ See the annex of Hussmanns (2003) for the overlap between informal employment and self-employment.

categorized into two groups based on their estimation methods. The first group encompasses indirect model-based estimates of the relative size of informal output (that is, informal output in percent of official GDP). The second group encompasses direct measures gathered from surveys, such as labor force, household, firm, or opinion surveys. In the database, indirect and direct measures together cover up to 196 economies (36 advanced economies and 160 EMDEs) and for periods as long as 1950-2018 (table 2.1.A).

This section describes the informality database and the limitations and advantages of each measure included in it. Indirect measures stand out for their broad country and long year coverage, but they suffer from their narrow focus on economic production and strong reliance on model specifications and assumptions. Direct measures capture more dimensions of informality and do not involve particular model specifications and assumptions, but they tend to have limited country and year coverage, making them less well suited to cross-country, time-series analyses. Indirect measures provide only a macro perspective on the extent of informality in an economy, whereas direct measures can also provide a micro perspective on how firms and workers behave in the informal sector.

Indirect estimates

Previous studies have used various indirect approaches to estimate the size of the informal sector, including the currency-demand approach (Ardizzi et al. 2014), the electricity-demand approach (Schneider and Enste 2000), the Multiple Indicators Multiple Causes (MIMIC) model (Schneider, Buehn, and Montenegro 2010), and the dynamic general equilibrium (DGE) model (Elgin and Oztunali 2012; Ihrig and Moe 2004; Orsi et al. 2014). Among all indirect estimation methods, the MIMIC and DGE models stand out in terms of their long time-series and broad country coverage. For this reason, the focus here is mainly on the use of MIMIC and DGE models to estimate the size of informal economic activity. To make the measures comparable with those in the literature, both DGE-based and MIMIC-based estimates are reported in percent of official GDP.

The multiple indicators multiple causes model (*MIMIC*). This is a type of structural equations models that can be used to estimate the relative size of informal economic activity. Two features of MIMIC are particularly important: first, it explicitly takes into account multiple possible causes of informal activity and captures multiple outcome indicators of it; second, it can readily be used to estimate informal activity across countries and over time. Other indirect approaches, like the currency-demand approach and the electricity-demand approach, condense all the features of informal activity across product and factor markets into just one indicator.⁵ The informal sector, however,

⁵The electricity-demand and currency-demand approaches suffer from limited data availability and are each subject to specific caveats. The electricity-demand model rests on the strong assumptions that all informal economic activity requires only the use of electricity, and the association between informal production and use of electricity is constant over time. The currency-demand approach rests on the assumption that transactions in the informal sector are paid in cash and that there is no informal sector in the base year (Ahumada, Alvaredo, and Canavesa 2007).

shows its effects in various markets, which can be captured better in a MIMIC model (Schneider, Buehn, and Montenegro 2010). The data on causes and indicators of informal activity identified in the literature are largely macroeconomic data in a panel setting and can be updated annually.

The limitations of the standard MIMIC model, used by Schneider, Buehn, and Montenegro (2010) and others, have been widely discussed in the literature (Feige 2016; Medina and Schneider 2018). The limitations include: 1) the use of GDP (that is, GDP per capita and its growth rates) as both cause and indicator variables, 2) its reliance on another, independent study's base-year estimates of the informal economy to calibrate the size of the informal economy in percent of GDP, and 3) the sensitivity of the model's estimated coefficients to alternative model specifications and sample coverage.⁶ These limitations can open the MIMIC estimates to charges of manipulation and misrepresentation (Breusch 2005).

The most cited MIMIC study, Schneider, Buehn, and Montenegro (2010), is replicated here to estimate the size of the informal sector in percent of official GDP. Six causes and three indicators are used in the estimation to capture the hypothesized relationships between the informal sector (the latent variable) and its causes and indicators (annex 2A). Once the relationships are identified and the parameters are estimated, the estimation results are used to calculate the MIMIC index, which gives the absolute values of the size of the informal sector after a benchmarking or calibration procedure. The estimates from the model specification that ensures maximum data coverage are used here (annex 2A). The MIMIC approach delivers a panel of estimates for 160 economies (36 advanced economies and 124 EMDEs) over the period 1993-2018.

The MIMIC estimates capture the combination of both employment and productivity in the informal sector, whereas measures of informal employment only reflect the level of employment in the informal sector. Despite the comprehensive country and long time-series coverage, MIMIC estimates do not fluctuate much over time, which makes the estimates less suited for time-series analyses (including the business cycle analysis below).

The DGE model (DGE). The dynamic general equilibrium (DGE) model considers how optimizing households will allocate labor between formal and informal economies in each period and how the allocation changes over time (Ihrig and Moe 2004; Elgin and Oztunali 2012). In comparison with other estimation methods, the DGE approach stands out in the comprehensive country and year coverage that it allows, its clear theoretical basis, and its applicability to policy experiments and projections (Loayza 2016).

The DGE approach has some limitations. First, it relies on strong assumptions about the functional form of activity in the informal and formal sector and about the

⁶ Medina and Schneider (2018) try to overcome the limitation of using official GDP (which may capture part of the informal economy) by using night-light data to independently capture economic activity.

relationship between formal and informal productivity (Orsi, Raggi, and Turino 2014; Schneider and Buehn, 2016). Second, like the MIMIC approach, it requires base-year estimates of the informal economy from another independent study to calibrate the size of informal economy (Elgin and Oztunali 2012; Ihrig and Moe 2004). Third, a computable DGE model only captures some of the stylized facts of the informal sector. Data availability, especially for EMDEs, presents a challenge to matching DGE models with all aspects of informality.

Here, a deterministic DGE model proposed by Elgin and Oztunali (2012) is used to estimate the size of the informal sector. The model captures the essence of labor allocation between the formal and informal sectors and provides a mapping between the formal and informal economies in a dynamic setting. The model relies on two key equilibrium conditions for calibration and data construction processes (annex 2A). The two key equilibrium conditions are one that connects the formal and informal economies through labor allocation, and another that captures intertemporal substitution. The model results in estimates of informal output in percent of official GDP for 158 economies (36 advanced economies and 122 EMDEs) over the period 1950-2018.

The DGE estimates reflect the levels of both employment and productivity in the informal sector and stand out in their broad country and long year coverage. The time variation of the DGE estimates is sufficient for time-series analysis, including the business cycle analysis in the following sections. But the time variation of the DGE estimates relies partially on strong assumptions. For instance, in Elgin and Oztunali (2012), the growth rate of productivity in the informal sector is assumed to be a function of the growth rates of capital and productivity in the formal sector.⁷

Survey-based estimates

Four existing informality measures are labor-related, of which three are related to employment and one to pension coverage. These measures are gathered mainly from labor force surveys but sometimes from household surveys.

Labor force surveys. Labor force survey-related measures have the advantages of not relying on strong assumptions, having no need for base-year estimates for calibration, and having sufficient time variation for time-series analysis. But they also have several limitations: the data are costly to gather, contributing to limited country and year coverage; survey methodologies may vary over time and across countries, limiting the comparability of the data; there are the typical drawbacks of survey-based data (such as sample bias); and employment measures cannot reflect other changes in the informal sector, such as in productivity and the number of working hours.

⁷In the case of Elgin and Oztunali (2012), the heavy reliance of DGE estimates on assumptions and base-year estimates on the informal economy for calibration could be reduced by using other sources of information on the informal economy (survey-based estimates of informal employment).

Despite the limitations, survey-based labor-related measures can provide useful guidance for the construction and use of indirect informality measures. Among all labor-related measures, self-employment stands out in its year and country coverage and sufficient time variation, making it suitable for time-series analysis and cross-country comparisons.⁸ For labor-related questions (employment creation and destruction in the informal sector, or social security issues), labor-related measures are typically preferred.

The most frequently used measure is the share of self-employment in total employment (in the database used here labeled *SEMP*; La Porta and Shleifer 2014; Maloney 2004). As defined by the 1993 International Classification of Status in Employment, self-employed workers include four sub-categories of jobs, as classified in the World Bank's World Development Indicators (WDI) and by the International Labour Organization (ILO): employers, own-account workers, members of producers' cooperatives, and contributing family workers.⁹ Self-employed workers are those who, working on their own account (own-account workers or employers) or with one or a few partners or in a cooperative, hold "self-employment jobs" as defined above. These are jobs where the remuneration is directly dependent upon the profits derived from the goods and services produced.

Two other measures are informal employment and employment outside the formal sector.¹⁰ These are usually expressed in percent of total employment (or non-agricultural employment) and refer to different aspects of informality.¹¹ Whereas employment outside the formal sector is an enterprise-based concept that includes persons employed by informal sector enterprises or in households, informal employment is a job-based concept and has a broader definition. Informal employment comprises all workers in the informal sector and informal workers outside the informal sector. Almost all persons employed in the informal sector are in informal employment. But not all informal employment is in the informal sector. For example, informal employment includes internships in the formal sector without contracts or pension contributions.

⁸ ILO also produces model-based estimates which it uses to construct an internationally comparable data set on the share of self-employment in total employment (<https://www.ilo.org/ilostat-files/Documents/TEM.pdf>). Such model-based estimates largely rely on collected survey-based estimates but still could be sensitive to model specifications. Over the period 1990-2018, the pairwise correlation between survey-based estimates on self-employment shares and model-based estimates is 0.95. For the purpose of this book, survey-based estimates of self-employment shares are preferred.

⁹ Self-employment largely overlaps with informal employment, but not all self-employed workers are in informal employment. For example, the owner of a formally registered firm is both self-employed and formally employed. Whereas contributing family workers are always classified as informal, workers who hold other types of "self-employment jobs" are classified as informal employment when their production units are informal sector enterprises or households. See 17th ICLS guidelines for details (<https://www.ilo.org/public/libdoc/ilo/2013/480862.pdf>).

¹⁰ ILO presents detailed definitions of these two measures (ILO 2021a, b). Here, the harmonized series of these two measures, which allow for cross-country comparisons, are preferred, despite some remaining limitations (ILO 2021c).

¹¹ ILO reports these two measures both in percent of total employment and in percent of non-agricultural employment. Due to space limitations, the analysis here focuses on these two measures in percent of total employment, which are comparable with the self-employment measure.

For a comprehensive dataset on labor-related measures on informality, cross-country databases, provided by the WDI, ILO and OECD, are combined, with additional data gathered from various sources (annex 2A). The resulting dataset on self-employment is a panel of 180 economies or regions over the period 1955-2018. The dataset on informal employment covers 72 EMDEs from various years during 2000-2018 whereas the dataset on employment outside the formal sector contains 76 EMDEs from various years during 1999-2018. Data on informal employment and on employment outside the formal sector are obtained from the ILO.

Data on pension coverage are gathered from various issues of the WDI (book version, reported until 2012). The measure is defined as the fraction of the labor force that contributes to a retirement pension scheme (Loayza, Servén, and Sugawara 2010). It yields a panel that covers 135 economies from 1990 to 2010. The measure is suitable for analyzing social security issues related to the informal economy.

Firm opinion surveys. Two datasets based on surveys of firms have outstanding coverage and data quality: the World Bank's Enterprise Surveys, and the Executive Opinion Surveys conducted by the World Economic Forum. The World Bank Enterprise Surveys cover 140 economies over the period 2006-2018 whereas Executive Opinion Surveys cover 154 economies over the period 2008-2018.¹²

Both surveys are answered by top managers and business owners, who can be expected to be familiar with the business climate in the country concerned. The surveys could reveal some dimensions of informality (for example, regarding the ease of doing business in the informal sector) that are not captured in the output or labor-related measures of informality. Similar to labor-related measures, measures from firm surveys also have the advantages of being independent of strong assumptions and base-year estimates for calibration.

There are two particular drawbacks of informality measures based on firm surveys. First, data from firm surveys tend to have limited year coverage. Second, since perceptions tend not to move much over time, these types of measures do not have much time variation. Both drawbacks limit their application in time-series analysis. Nonetheless, they shed light on the perceived extent of informality in a country and can provide useful guidance for constructing and validating indirect model estimates.

World Bank Enterprise Surveys compile responses on various topics (including informality) from face-to-face interviews with top managers and business owners in over 161,000 companies in 144 economies. The surveys yield the following measures of informality that have been used in the literature (La Porta and Shleifer 2014; World Bank 2019a): percent of firms competing against unregistered or informal firms (*WBI*),

¹² Due to survey design changes, the data collected by the Executive Opinion Surveys over the period 2004-2007 are not comparable with those for subsequent years. The World Bank also conducts Productivity and Investment Climate Surveys at the firm level. Although these surveys occasionally report measures of informality, they are obtained from various sources and use different methodologies.

percent of firms formally registered when they started operations in the country (*WB2*), (average) number of years firms operating without formal registration (*WB3*), and percent of firms identifying practices of competitors in the informal sector as a major constraint (*WB4*). Higher values of *WB1*, *WB3* and *WB4* and a lower value of *WB2* indicate higher levels of informality. *WB1* and *WB4* also provide some insights into informal firms' competitiveness whereas *WB2* and *WB3* are considered indicative of constraints imposed by registration requirements.

In comparison to Enterprise Surveys, Executive Opinion Surveys provide a more balanced panel dataset, making them more suitable for business cycle analysis. The World Economic Forum (*WEF*) has been conducting Executive Opinion Surveys every year since 1979. As reported in the 2014 edition, over 13,000 executives in 144 economies were surveyed. From 2006, the survey has asked the question, "In your country, how much economic activity do you estimate to be undeclared or unregistered? (1 = Most economic activity is undeclared or unregistered; 7 = Most economic activity is declared or registered)." The average responses at the country-year level constitute a series of informality measures with a lower average indicating a relatively larger informal economy.

Household surveys. Household surveys may report perceptions of the extent of informality in an economy or opinions on informal economic activities. The World Values Survey (*WVS*) stand out in terms of their extensive country and year coverage; others household surveys mainly focus on European economies.¹³ The *WVS* asked whether respondents considered it justifiable to cheat on taxes, with the data averaged for five periods from 1981-1984 to 2010-2014. The responses could range from 1 (never justifiable) to 10 (always justifiable). In total, 317,750 respondents from 96 economies participated in the survey. The average responses at the country and year level are used as a measure for attitudes towards informality. A higher average at the country level implies that people find cheating on taxes more justifiable and thus consider informal activity more acceptable. It is regarded as an indirect measures of informality as a lack of tax morality is associated with a higher level of informality (Oviedo, Thomas, and Karakurum-Özdemir 2009).

Comparison of statistical features across measures

For any economy, the various measures of informality will differ somewhat, both in the level of informality implied and in its variation over time. In general, MIMIC estimates indicate lower and less volatile informal sector activity than DGE estimates. This partly reflects the differences in the assumed underlying drivers of informality in the two approaches: MIMIC is based on slow-moving variables such as ones relating to institutional quality whereas DGE is based on more volatile variables such as employment, investment and productivity. In EMDEs, the share of informal activity in

¹³ These surveys, which include the Eurobarometer Survey, European Values Survey, and the European Social Survey, are not used in this study because of their limited coverage of EMDEs. Details about other social surveys are shown in annex 2A (tables 2.1.A and 2.9).

GDP (by either measure) tends to be well below the share of self-employment in total employment, which may reflect lower labor productivity in the informal economy than the formal economy or some self-employed workers contributing to the formal economy (Loayza 2018).¹⁴ Survey-based measures tend to be stable over decades, potentially reflecting a profound rigidity in perceptions.

Size and evolution of the informal economy

This section distills the empirical findings on the main features of the informal economy and its evolution over time. The informal economy is more prevalent in EMDEs than in advanced economies but is widely heterogeneous across countries and regions. Both output and employment measures of informality have trended downward since 1990. In contrast, survey-based measures relating to perceptions have tended to be highly stable, making them more appropriate for cross-country comparisons than for over-time analyses.

About one-third of activity. Globally, the informal economy accounted for 32-33 percent of GDP and 31 percent of employment over the period 1990-2018 (table 2.1.B). As shown in previous studies, a higher level of development, as measured by per capita income, is associated with lower informality, virtually regardless of the measure of informality, other than survey-based ones, or the year chosen (La Porta and Shleifer 2014). Thus informality tends to be considerably more pervasive in EMDEs than in advanced economies (figure 2.2): in advanced economies, it accounts for about 19 percent of GDP and 16 percent of employment, on average, whereas in EMDEs it accounts for 36-37 percent of GDP and 39 percent of employment.

Wide cross-country heterogeneity. There is wide heterogeneity in informal activity among EMDEs (figure 2.2). For example, the informal economy's share in GDP, while depending on the measure used, ranged from around 10 percent to 68 percent, and the share of self-employment in total employment ranged from near-zero to 96 percent.

Widespread informality across all EMDE regions. Informality is common in all EMDE regions but takes different forms (World Bank 2012). On average, the informal economy's share of output is highest in SSA, Europe and Central Asia (ECA), and Latin America and the Caribbean (LAC). The share of self-employment, however, is highest in SSA, South Asia (SAR), and East Asia and the Pacific (EAP; figure 2.3).

Declining employment and output informality over time. The shares of both informal output and employment have declined since 1990, especially in EMDEs (figure 2.4).

¹⁴In this section and below, self-employment is used to proxy for informal employment as in La Porta and Shleifer (2014), unless otherwise specified. In the following sections, "in percent of GDP or output" is used as the equivalent of "in percent of official GDP" in the context of the share of informal output (both DGE-based and MIMIC-based estimates), and "in percent of employment" is used as the equivalent of "in percent of total employment."

FIGURE 2.2 Informality and development

Informality is more pervasive in emerging market and developing economies (EMDEs) than in advanced economies, indicating a positive link between development and informality. But informality varies widely among EMDEs.

A. DGE-based informal activity

B. MIMIC-based informal activity

C. Self-employment

D. Labor force without pension

E. Perceived informal activity

F. Attitudes to informality

Sources: World Bank; World Economic Forum; World Values Survey.

Note: See table 2.1.A for details on data definitions. Simple group means for the period 2010-2018 (2000-2010 for D and F due to data availability) are shown in bars with their -1 and +1 standard deviation (SD) shown by orange whiskers. DGE = dynamic general equilibrium model-based estimates of informal output in percent of official GDP; EMDEs = emerging market and developing economies; MIMIC = multiple indicators multiple causes model-based estimates of informal output in percent of GDP.

C. Missing data for self-employment in percent of total employment are interpolated in EMDEs for earlier years and filled using the latest available observation in recent years.

D. "Labor force without pension" is in percent of labor force, averaged over 2000-2010, given data availability.

E. WEF (World Economic Forum) index of perceived informality is used.

F. Data from World Values Survey on the attitude towards cheating on taxes are used here and averaged over 2000-2010, given data availability.

FIGURE 2.3 Informality in EMDE regions

Informality is common in all EMDE regions but takes different forms. On average, the share of informal output is highest in Sub-Saharan Africa, Europe and Central Asia, and Latin America and the Caribbean. The share of self-employment is highest in Sub-Saharan Africa, South Asia, and East Asia and the Pacific.

A. DGE-based informal activity

B. MIMIC-based informal activity

C. Self-employment

D. Labor force without pension

E. Perceived informal activity

F. Shares of EMDE regions in world output and employment

Sources: International Labour Organization; World Bank (World Development Indicators); World Economic Forum.

Note: Blue and red bars indicate group means for 2010-18 (2006-2016 for D), with whiskers indicating ± 1 standard deviation. DGE = dynamic general equilibrium model-based estimates on informal output; EAP = East Asia and Pacific; ECA = Europe and Central Asia; EMDEs = emerging market and developing economies; LAC = Latin America and the Caribbean; MIMIC = multiple indicators multiple causes model-based estimates on informal output; MNA = Middle East and North Africa; SAR = South Asia; SSA = Sub-Saharan Africa.

C. Self-employment shares (in percent of total employment) is used here.

E. Perceived informal activity is proxied by World Economic Forum Index, which ranges from "1= Most economic activity is undeclared or unregistered" to "7 = Most economic activity is declared or registered". See table 2.1.A for details on data definitions.

F. The stacked bars show the formal and informal output (employment) in each EMDE region as a share of the world's total formal or informal output (employment) using data averaged from 2010-18. Formal output is proxied by official GDP, while DGE-based estimates are used to capture the level of informal output. Informal employment is proxied by self-employment, while formal employment is the difference between total employment and self-employment.

FIGURE 2.4 Evolution of informality in advanced economies and emerging market and developing economies, 1990-2018

The shares of informal employment and output have declined in both advanced economies and emerging market and developing economies (EMDEs) since 1990, despite largely unchanged perceptions of the size of the informal sector.

A. DGE-based informal activity

B. MIMIC-based informal activity

C. Self-employment

D. Perceived informal activity

Source: World Bank; World Economic Forum.

Note: See table 2.1.A for details on data definitions. Group means are calculated for advanced economies (in blue) and emerging market and developing economies (EMDEs, in red). DGE = dynamic general equilibrium model; MIMIC = multiple indicators multiple causes model.

C. Informal employment is proxied by self-employment in percent of total employment. Missing data for self-employment are interpolated in EMDEs for earlier years and filled using the latest available observation in recent years.

D. WEF (World Economic Forum) index of informality is used, which ranges from "1= Most economic activity is undeclared or unregistered" to "7 = Most economic activity is declared or registered".

Between 1990 and 2018, on average, the share of informal output in GDP fell by about 8 percentage points in EMDEs, to 31 percent, and by 3 percentage points in the advanced economies, to 17 percent. Over the same period, the average share of self-employment in total employment declined by about 3 percentage points in the advanced economies, to 14 percent, and by about 10 percentage points in EMDEs, to 36 percent. In EMDEs, the largest declines in the shares of informal output and employment occurred from the early-2000s, in a reversal of a decade of a rising share of informal employment and barely shrinking share of informal output.¹⁵ In advanced

¹⁵The persistence of high levels of informality in EMDEs in the early 1990s in part reflects the expanding informal sector in Eastern and Central European economies during their economic transition (Kaufmann and Kaliberda 1996). By construction, slow-moving indicators for institutional quality in MIMIC estimates dampen these estimates' movements over time.

economies, the largest declines in the share of informal employment occurred between the late 1990s and the global financial crisis of 2008-09; they have since partly reversed, amid anemic post-crisis growth (figure 2.4).

Broad-based declines. The declines in informality between 1990 and 2018 were broad-based, especially for output- and employment-based measures. Country-specific regressions of the shares of the informal economy in GDP and employment on a time trend were estimated to capture this secular decline (figure 2.5). In 69 (*SEMP*)-100 (*DGE*) percent of advanced economies (depending on the measure) and 54 (*SEMP*)-81 (*MIMIC*) percent of EMDEs, statistically significant downward trends in the share of the informal economy in GDP (or employment) were found. The trend decline in the share of informal output suggests that economic growth may be associated with more rapidly rising labor productivity in the formal economy than in the informal economy. As economies grow, formal-sector productivity growth may benefit from greater technological improvements and availability of capital than can be accessed by the informal sector (Amaral and Quintin 2006). In only a few cases did output and employment informality move in different directions. Noticeable drops in the share of informal output were associated with only moderate falls in the share of informal employment in some EMDEs, and even with increases in the share of informal employment in others (see chapter 5 for detailed discussion).

Stable perceptions of informality over time. Perceptions of informality appear to have changed much more slowly than actual informal output and employment.¹⁶ In the majority of advanced economies and EMDEs, perceptions of the scale of informality—as measured by the *WEF* and *WVS* indices—have not declined significantly since 1990. There are, however, a few exceptions. This often coincided with rapid GDP growth and reductions in the shares of both informal output and employment.

Consistency among the various measures of informality

The various measures of informality refer to three distinct aspects of it: output (*DGE* and *MIMIC* estimates), employment (for example, self-employment and workers without pensions), and perception (for example, the *WEF* and *WVS* surveys). This section explores the consistency among the various measures of informality.

Correlations in cross-country rankings: Output and employment. The various measures for informality are generally positively correlated with each other, with the correlations within each block (output, employment, perception) being stronger than correlations between blocks (table 2.2). The cross-country rank correlation between the two model-based estimates of informal output is close to 1 and significantly different

¹⁶ Guiso, Sapienza, and Zingales (2009) demonstrate that perceptions of trustworthiness are largely historically determined with limited time-variance.

FIGURE 2.5 Downward trends in informality, 1990-2018

Informality declined in both advanced economies and emerging market and developing economies (EMDEs) during 1990-2018. The share of informal output dropped in all EMDE regions, but by most in East Asia and Pacific, Latin America and the Caribbean, and South Asia.

Source: World Bank; World Economic Forum.

Note: Data are for the period 1990-2018. DGE = dynamic general equilibrium model; EAP = East Asia and Pacific; ECA = Europe and Central Asia; EMDEs = emerging market and developing economies; LAC = Latin America and the Caribbean; MIMIC = multiple indicators multiple causes model; MNA = Middle East and North Africa; SAR = South Asia; SEMP = self-employment in percent of total employment; SSA = Sub-Saharan Africa; WEF = World Economic Forum estimates.

A. The bars indicate the simple group means for advanced economies and EMDEs, with the red bars for self-employment (in percent of total employment) and blue bars for DGE-based informal output (in percent of official GDP). Lines show world averages.

B. The bars indicate the simple group means for EMDE regions, with red bars for self-employment (in percent of total employment) and blue bars for DGE-based informal output (in percent of official GDP). Lines show EMDE averages.

C,D. Data for the period 1990-2018. Based on country-specific linear regressions of the share of informality on each of the four measures of informality with a sufficiently long-time dimension. Figures show the share of advanced economies (C) and EMDEs (D) for which the time trend is statistically significantly negative (at least at the 10 percent level). In D, missing values for self-employment are interpolated. Horizontal line indicates 50 percent.

from zero at the 1 percent level. In addition, the rank correlations between DGE estimates and both employment measures and some perception measures are also positive and significant (figure 2.6). The correlations among the various measures of informal employment range from 0.20 to 0.94 and are mostly significant at the 10 percent level. On average, the correlation between an estimate of informal output and employment-based measures is above 0.60 and significant at the 1 percent level.

Correlations in cross-country rankings: Perceptions. Perception-based estimates of informality tend to be more correlated with each other than with estimates of informal output or employment. The *WVS* is an exception: it tends to be uncorrelated or little

correlated with all other measures, including perception-based ones. This suggests that a large informal sector reflects more than citizens' weak tax morality, which *WVS* purports to capture. Among the perception-based measures, the *WEF*, which purports to capture perceptions of the extent of informal economic activities, is the one most correlated with the other measures, both output-based (about 0.70) and employment-based (about 0.5-0.7 with the share of labor force without pension and self-employment as a share of total employment).

Correlation in direction of movements over time. To examine the consistency of movements over time among various measures, the coincidence of the directions of movements in different variables is checked by looking at the shares of country-pairs in which first differences in two measures have the same sign (figure 2.6; table 2.3).¹⁷ This is the case in about 50 percent of all the country pairs—and highest, at 82 percent of country-year pairs, for informal employment and employment outside the formal sector. The directions of changes in output measures and employment measures coincide in 55-65 percent of country-year pairs, suggesting that output measures capture important additional factors to employment measures, such as changes in labor productivity or intensity of work.

Cyclical features of the informal economy

Like formal economies, informal economies feature business cycles, which share some features with those in the formal economy: They are stronger in EMDEs than in advanced economies, and they feature downturns and recoveries with similar speeds. That said, they are not fully synchronized with business cycles in the formal economy. This section distills the main cyclical features of the informal economy. Building on this section, chapter 3 explores the links between formal and informal business cycles in greater detail and their implications for macroeconomic policy.

Volatility of formal and informal economies

Employment and output volatility. The business cycles of formal and informal economies are not entirely synchronous (as discussed in detail in chapter 3). Employment growth in the informal sector is slightly, but statistically significantly, negatively correlated with employment growth in the formal sector (-0.2 percent). As a result, formal and informal employment alone are each more volatile than total employment (the sum of formal and informal employment).¹⁸

¹⁷As a robustness check, the pairwise correlations of first-differenced informality measures over time for each country are calculated, with their medians computed across countries. The results are in line with table 2.3. Whereas significant and positive correlations are observed among pension coverage, informal employment, and employment outside the formal sector, no significant correlations between informal employment (or perception) measures and informal output measures are found.

¹⁸This supports earlier findings that the informal sector may help stabilize total employment over business cycles (Fernández and Meza 2015; Loayza and Rigolini 2011).

FIGURE 2.6 Consistency among various informality measures

The various measures for informality are generally positively correlated with each other, with the correlations within each block (output, employment, perception) being stronger than correlations between blocks.

A. Correlations between DGE estimates and other informality estimates

B. Correlations between self-employment and other informality measures

C. Correlations between self-employment and other labor-related informality measures

D. Correlations between WEF index and other perception-related informality measures

E. Coincidence of signs of first differences: DGE estimates and other informality estimates

F. Coincidence of signs of first differences: Self-employment estimates and other informality estimates

Sources: World Economic Forum (WEF); World Bank (Enterprise Surveys); World Values Survey.

Note: Data for the period 1990-2018. DGE = dynamic general equilibrium model; MIMIC = multiple indicators and multiple causes model; SEMP = self-employment in percent of total employment; WEF = World Economic Forum estimates; WVS = World Values Survey. Pension coverage is in percent of labor force, while informal employment and employment outside the formal sector are in percent of total employment. WVS asks whether cheating on taxes is justifiable (1 is "never justifiable" and 0 is "always justifiable") and reports average responses at the country-year level. A higher level indicates a country is more tolerant of informality. WEF asks, "In your country, how much economic activity do you estimate to be undeclared or unregistered? (1 = Most economic activity is undeclared or unregistered; 7 = Most economic activity is declared or registered) and reports average responses at the country-year level. Here, the average responses have been reordered to make "7 = most economic activity is undeclared or unregistered" and "1 = most economic activity is declared or registered" such that a higher score indicates more informality (see also tables 2.1 and 2.2).

A.-D. Medians of rank correlations of data across countries within each year. All survey-based measures are interpolated. *** implies significance at 10 percent level. The responses from World Bank Enterprise Surveys are shown in D (see table 2.3 for details).

E.F. Shares of country-year pairs where first differences of DGE estimates (E) or self-employment (F) coincide with first differences of other informality estimates. Survey-based estimates are interpolated to fill gaps in data series.

FIGURE 2.7 Volatility of formal and informal economies, 1990-2018

Formal and informal output and employment are significantly more volatile in EMDEs than in advanced economies, possibly reflecting larger shocks to, or less resilience to shocks in, EMDEs.

Source: World Bank.

Note: Data are for the period 1990-2018. DGE = dynamic general equilibrium model; MIMIC = multiple indicators and multiple causes model. Formal output is captured by official GDP, while informal output uses DGE-based or MIMIC-based estimates. "Total employment" is the sum of formal employment and self-employment. Volatility shows the standard deviations (SDs) of the concerning variables' annual growth rates. *** indicates significant differences at 5 percent level between advanced economies and emerging market and developing economies (EMDEs).

Volatility in EMDEs and in advanced economies. Formal and informal output and employment are significantly more volatile in EMDEs than in advanced economies, possibly reflecting larger shocks, or lesser resilience to shocks, in EMDEs (figure 2.7; table 2.4; Aguiar and Gopinath 2007; Neumeyer and Perri 2005; Restrepo-Echavarría 2014).¹⁹ In addition, in both EMDEs and advanced economies, self-employment is somewhat more volatile than formal employment (that is total employment excluding self-employment), perhaps reflecting greater rigidity in the formal labor market (Djankov and Ramalho 2009).

Informal-economy business cycles

Dating informal business cycles. Formal and informal business cycles were identified using the commonly used algorithm of Harding and Pagan (2002). Business cycle turning points are years in which output peaks or troughs. When there are several peaks or troughs within a five-year interval, the deepest trough or steepest peak was used. A recession is defined as the period from peak to trough, whereas an expansion is the converse, the period from trough to peak. A recovery, the early part of an expansion, is defined as the period during which output rebounds from the trough to its pre-recession peak. The main characteristics of the recession and recovery phases, including duration, amplitude, and slope, are defined as in Claessens, Kose, and Terrones (2012; annex 2A). Following Kose, Otrok, and Whiteman (2003), employment was logged, first differenced and demeaned to remove trend employment growth.

¹⁹ Detailed results on the volatility of formal and informal economies are presented in table 2.4.

The results are in line with earlier studies (Bajada 2003; Birinci and Elgin 2013) of informal business cycle recessions and expansions in advanced economies.²⁰ In contrast to these studies, however, the main focus here is on recessions and recoveries. Since recoveries are the early parts of expansions, they reflect more of an economy's short-term cyclical movements rather than its long-term growth path.

Output movements through informal-economy business cycles. Neither recessions nor recoveries in the informal economy differ statistically significantly from those in the formal economy (figure 2.8; tables 2.5.A and 2.5.B). The duration of both formal- and informal-economy recoveries was slightly longer than formal- and informal-economy recessions in EMDEs but not in advanced economies.²¹ The speed of recessions resembled that of recoveries in both formal and informal economies. As for formal economies, informal-economy recessions were steeper and informal economy recoveries were stronger in EMDEs than in advanced economies. As a result, output and employment in EMDEs tended to be more volatile than in advanced economies—a feature well documented in the literature (Aguiar and Gopinath 2007). One of the reasons could be the tendency for fiscal policy to be procyclical in EMDEs, exacerbating the underlying business cycle (Frankel, Végh, Vuletin 2013).

- *Recessions.* The average DGE-based informal economy recession lasted 1.5 years, with a GDP contraction, on average, of 3.5 percent per year, 5.2 percent from peak to trough, and 5.7 percent cumulatively—broadly in line with formal economy recessions.²² Both formal-economy and informal-economy recessions were significantly shallower in advanced economies than in EMDEs.
- *Recoveries.* On average, output in both formal and informal economies took about 2 years to return to their pre-recession peaks, expanding by 2–6 percent in the first year and by 2–5 percent per year during the entire recovery phase.²³ Like formal-economy recoveries, informal-economy recoveries were significantly shallower in advanced economies than in EMDEs.

Informal employment during informal-economy business cycles. Informal employment, proxied by self-employment, in both advanced economies and EMDEs was broadly stable in informal recessions as well as recoveries. This finding applies to both formal and informal economy business cycles (figure 2.9; table 2.6.A). This may be because wage movements or changes in work intensity (measured as number of hours

²⁰ A comparison between findings here and former studies will be provided upon request.

²¹ The differences in durations between recessions and recoveries are not significant for EMDEs when using MIMIC-based estimates.

²² The recessions of MIMIC-based informal output are slightly shallower and more prolonged than those of formal output and DGE-based informal output (tables 2.5.A and 2.5.B). The slightly shallower recessions of MIMIC-based informal output could be due to the slow-moving institutional measures embedded in MIMIC's estimation methods (for example, government effectiveness).

²³ MIMIC-based informal recoveries were significantly shorter, occurred less frequently, and were less pronounced than DGE-based informal recoveries and formal recoveries.

FIGURE 2.8 Cyclical features of formal and informal business cycles

In most cases, informal-economy recessions and recoveries do not differ statistically significantly from formal-economy recessions and recoveries. Meanwhile, both formal- and informal-economy recessions and recoveries are less pronounced in advanced economies than in EMDEs.

A. Recessions in formal output

B. Recoveries in formal output

C. Recessions in DGE-based informal output

D. Recoveries in DGE-based informal output

E. Recessions in MIMIC-based informal output

F. Recoveries in MIMIC-based informal output

Source: World Bank.

Note: Data for recession (recovery) episodes starting and ending in the period 1990-2018. Business cycle turning points determined on the basis of formal and informal GDP levels (that is, official GDP statistics for formal output, and DGE and MIMIC estimates for informal output) using the algorithm of Harding and Pagan (2002). DGE = dynamic general equilibrium model; MIMIC = multiple indicators and multiple causes model. Recession is defined as the phase from peak to trough, while recovery is defined as the phase from the trough in output to its peak level before the recession (Claessens, Kose, and Terrones 2012). The "duration" captures the period from peak to trough for a recession, and the period it takes for output to return to its pre-trough peak for a recovery. The "amplitude" of a recession measures the change in output from a peak to the next trough. The amplitude of a recovery measures the change in output during the first year of an expansion, which is the period between a trough and its following peak. EMDEs = emerging market and developing economies.

A-F. Bars show simple group means and diamonds show group medians. *** implies that differences between advanced economies and EMDEs are significant at 10 percent level.

FIGURE 2.9 Employment changes during formal and informal business cycles

Total and formal employment contracted significantly during formal economy recessions in advanced economies but remained largely stable in emerging market and developing economies (EMDEs). Self-employment in both advanced economies and EMDEs did not change significantly in either recessions or recoveries. The lack of response was found in cycles in both formal and informal economies.

A. Changes in total employment during formal business cycles

B. Changes in formal employment during formal business cycles

C. Changes in self-employment during formal business cycles

D. Changes in self-employment during informal business cycles

Source: World Bank.

Note: Data for the period 1990-2018. Business cycle turning points determined based on formal and informal GDP levels (that is, official GDP statistics for formal output and DGE-based estimates for informal output) using the algorithm of Harding and Pagan (2002). Recession is defined as the phase from peak to trough, while recovery is defined as the phase from the trough in output to its peak level before the recession (Claessens, Kose, and Terrones 2012). DGE = dynamic general equilibrium model; EMDEs = emerging market and developing economies.

A.-D. Bars show simple group means of overall changes in employment during business cycle phases. *** implies that numbers that significantly differ from zero at 10 percent significance level. EMDEs with poor statistical capacity and three outliers (Democratic Republic of Congo, Gabon, and Zimbabwe) were dropped.

worked per day) bore the brunt of the adjustment in labor markets during business cycles (Guriev, Speciale, and Tuccio 2019; Meghir, Narita, and Robin 2015).

Formal and total employment during formal-economy business cycles. Total and formal employment in advanced economies behaved significantly differently from in EMDEs during formal economy recessions and recoveries (tables 2.6.A and 2.6.B). Both total and formal employment contracted significantly (by 2.5 and 2.7 percent, respectively) in advanced economies during formal economy recessions, while neither

total nor formal employment fell significantly in EMDEs. Employment changes during formal-economy recoveries were insignificant in both advanced economies and EMDEs. The lack of significant responses in employment during formal economy recoveries suggests delayed responses in the labor market and the emergence of “jobless” recoveries in recent decades (Farbar 2012; Hall 2005; Shimer 2010 and 2012).

Conclusion

The compilation of a comprehensive database of model-based and survey-based estimates of informal economic activity provides a rich set of measures available for cross-country analysis and a more limited set of measures available for time-series or panel analysis. Among all the measures, DGE-based estimates and survey-based estimates of self-employment stand out in their cross-country and year coverage. In contrast, survey-based measures of perceptions tend to be highly stable over time and, therefore, are mainly useful for cross-country comparisons. Lastly, for cross-country analyses of narrowly-defined questions, measures from labor, firm, and household surveys may be more suitable, especially when surveys are done consistently.

Two applications of the constructed database are illustrated in this chapter. First, using the widest possible range of measures, the chapter illustrates the broad-based and steady decline in the shares of informal output and employment since 1990. Three somewhat distinct aspects of informality are identified: output, employment, and perceptions. Cross-country rankings of informal output or employment are typically consistent with each other while varying over time.

Second, the chapter documents that informal economies experience business cycles just as formal economies do. Like formal-economy output cycles, informal-economy output cycles tend to be shallower in advanced economies than in EMDEs. Informal employment tends to behave acyclically in EMDEs and advanced economies, largely invariant to both output recessions and recoveries. In contrast to distinct cyclical movements in informal output, perceptions of the scale of informality shown by surveys are highly persistent.

Several possible areas for further research are worth noting. First, the limitations and weaknesses of all existing measures of informality remain, despite the richness of the database compiled here. More work is needed to improve the quality of existing measures and to explore new approaches to better capture the extent of informality in EMDEs. Second, the chapter distills the main features of informal economy business cycles. It does not look into the factors and policies that could affect informal economy business cycles. Further analyses in this direction would be valuable.

ANNEX 2A Estimation methodologies

The following section describes the estimation methodologies for concerning informality measures. Detailed data description is listed in table 2.7.

The multiple indicators multiple causes model (MIMIC model)

To estimate the size of the informal sector in percent of official GDP with the MIMIC model, this study closely follows Schneider, Buehn, and Montenegro (2010) and includes six causes and three indicators used in their study.²⁴ The six cause variables used are: 1) size of government (general government final consumption expenditure as a percent of GDP, from UN spliced with WDI); 2) share of direct taxation (direct taxes in percent of overall taxation, WDI); 3) fiscal freedom index from Heritage Foundation; 4) business freedom index from Heritage Foundation; 5) the unemployment rate and GDP per capita to capture the state of the economy (WDI, the latter is spliced with WEO); and 6) government effectiveness (Worldwide Governance Indicators). The three indicator variables include: 1) growth rate of GDP per capita (WDI, spliced with WEO); 2) the labor force participation rate (people over 15 economically active in percent of population, WDI, spliced with Haver Analytics), and 3) currency as a ratio of M0 (currency outside the banks) over M1 (IMF IFS and Haver Analytics).

The estimation results are shown in table 2.8. The model specification that ensures maximum data coverage, which is shown in column 5 of table 2.8, is used to generate the MIMIC index of the share of informal output relative to official GDP ($\tilde{\eta}_t$). Then an additional benchmarking procedure is carried out where t is converted into absolute values of the informal sector ($\hat{\eta}_t$) using the following equation:²⁵

$$\hat{\eta}_t = \frac{\tilde{\eta}_t}{\tilde{\eta}_{2000}} \eta_{2000}^*, \quad (1)$$

where t denotes year, $\tilde{\eta}_{2000}$ is the value of the estimated index in the base year 2000, and η_{2000}^* is the exogenous estimate (base value) of the shadow economies in 2000. While the estimates ($\tilde{\eta}_t$) determine the movement of the absolute values of the informal sector over time, the base values η_{2000}^* decide the rankings of the countries' informal sector within the sample in year 2000. The base values η_{2000}^* are taken from Schneider (2007) or, for another 10 economies, from Schneider, Buehn, and Montenegro (2010).

The dynamic general equilibrium model (DGE)

In the model of Elgin and Oztunali (2012), an infinitely lived representative household is endowed with K_0 units of productive capital and a total of $H_t > 0$ units of time. The

²⁴ MIMIC is a type of Structural Equation Model (SEM). The estimation of a SEM with latent variables can be done by means of LISREL (used by Schneider, Buehn, and Montenegro 2010), SPSS, and Stata. Here, Stata is used.

²⁵ Calibration is performed separately for each country. Following Schneider, Buehn, and Montenegro (2010), the MIMIC index has been adjusted to the positive range by adding a positive constant.

household has access to two productive technologies, denoted formal and informal, and maximizes its lifetime utility by solving the following optimization problem:

$$\max_{\{C_t, I_t, K_{t+1}, N_{Ft}, N_{It}\}_{t=0}^{\infty}} \sum_{t=0}^{\infty} \beta^t U(C_t)$$

$$s.t. \quad C_t + I_t = (1 - \tau_t) A_{Ft} K_t^\alpha N_{Ft}^{1-\alpha} + A_{It} N_{It}^\gamma \quad (2)$$

$$K_{t+1} = I_t + (1 - \delta) K_t \quad (3)$$

$$N_{It} + N_{Ft} = H_t \quad (4)$$

$\beta < 1$ is a discount factor and the instantaneous utility function $U(\cdot)$ is strictly increasing and strictly concave. Eq(2) defines the household's resource feasibility constraint: the sum of consumption C_t and investment I_t should equal the amount produced using the formal and informal technologies. The right-hand side of Eq(2) shows that the formal technology (A_{Ft}) follows a standard Cobb-Douglas specification and is exclusive to the formal sector. K_t is the household's capital stock while N_{Ft} is the number of hours the household devotes to the formal sector. τ_t captures the tax rate imposed on formal output. Informal output depends on the number of hours the household devotes to the informal sector, N_{It} , and its technology, A_{It} .²⁶

The rest of the household's problem is standard: Eq(3) specifies the law of motion for capital, where $\delta \in [0; 1]$ is the depreciation rate. Eq(4) is the household's time constraint. In this simple model, the government's policy τ_t is assumed to be exogenously given and the tax revenue is assumed to be used to finance an exogenous stream of government spending, G_t . Then, given the government policy variable tax burden, $\{\tau_t\}$ a competitive equilibrium of the two-sector model is a set of sequences $\{C_t, I_t, K_{t+1}, N_{Ft}, G_t\}_{t=0}^{\infty}$ that maximize the expected utility from consumption, which is $\sum_{t=0}^{\infty} \beta^t U(C_t)$.

The model provides a mapping between the formal economy and informal economy in a dynamic setting. The two key equilibrium conditions are the equilibrium condition that connects the formal and informal economy through labor allocation, and the equilibrium condition that captures the intertemporal substitution. The calibration and data construction processes rely on these two conditions to estimate the ratio, $\frac{Y_{It}}{Y_{Ft}}$, which can be further expressed as $\frac{A_{It} N_{It}^\gamma}{A_{Ft} K_t^\alpha N_{Ft}^{1-\alpha}}$.

The calibration follows Elgin and Oztunali (2012) and takes parameter values suggested by the earlier literature (for example, Ihrig and Moe 2004).²⁷ α is assumed to be equal to 0.36, and γ takes the value of 0.425. Data are gathered from PWT 9.1 for capital stock (K_t), private consumption (C_t), formal employment (N_{Ft}), depreciation rates (δ , country averages), and tax rates (τ_t). By matching the productivity in the informal sector to the

²⁶ The model also assumes no cost for hiding income, that the government cannot enforce payment of taxes, and the household will attempt to hide any income received from the informal sector.

²⁷ Elgin and Oztunali (2012) are not using the model to do a full calibration exercise (where each equilibrium condition is satisfied for every period). Since only two of the equilibrium conditions are utilized, stationarity of empirical data for calibration is a lesser concern. Their approach is followed here.

informal economy size in 2007 of the series reported in Schneider, Buehn, and Montenegro (2010) and assuming that A_{It} grows at the average growth rate of K_t and A_{Ft} ,²⁸ the DGE estimates are computed for 158 economies over the period 1950-2018.

The estimation results are qualitatively robust to different model specifications like using alternative values for δ , α , γ , or adding labor-leisure choice, tax enforcement parameter to informal sector income. See Elgin and Oztunali (2012) for details.

Labor-related measures of Informality

Several cross-country databases report the survey-based estimates on the share of self-employment in total employment:²⁹ 1) the 2016 World Development Indicators (World Bank 2016), which cover 175 economies from 1980 (mainly from 1990s) to 2014; 2) the International Labour Organization (2016), which covers 109 economies from 1997 to 2014; and 3) aPeOECD (updated in 2016, 2018, and 2020), which covers 34 OECD countries from 1955 to 2018. When regarding employment outside the formal sector and informal employment, ILO compiled statistics for up to 76 middle- and low-income countries for 1999-2018.

For a comprehensive dataset on labor-related measures on informality, we combine the cross-country databases, provided by WDI, ILO, and OECD, and gather additional data from the national statistical bureaus (offices), Haver Analytics, the disclosed Living Standards Measurement Studies (LSMS, World Bank), and spliced data from IADB and Eurostat to fill some gaps in years. Data priority is first given to cross-country databases (World Bank, ILO, and OECD) and then national statistical bureaus (offices), Haver Analytics, and LSMS, followed by estimates obtained from previous studies, IADB and Eurostat. IADB reports the share of self-employment in total employment (15-64 years old) for 19 Latin American economies between 1990 and 2018, while Eurostat reports the same measure for 29 EU economies and 5 non-EU economies for the period 1983-2018. By focusing on employment of the 15-64 years old groups, their data are systematically lower than those from other cross-country databases. The final step adds 105 more observations to the sample (3 percent of the full sample).

The national statistical bureaus (offices) that provided data or were contacted are: Angola, Argentina, Azerbaijan, The Bahamas, Bahrain, Belarus, Belize, Benin, Bhutan, Bosnia and Herzegovina, Botswana, Brunei Darussalam, Bulgaria, Burkina Faso, Burundi, Cabo Verde, Cambodia, Cameroon, Central African Republic, Chad, China, Comoros, Croatia, Cyprus, Democratic Republic of Congo, Republic of Congo, Arab

²⁸ This assumption implies that growth in the formal sector can spill over to the informal sector via capital accumulation and technological diffusion.

²⁹ Both ILO and WDI only report model-based estimates from 2018 onward, which may suffer from caveats such as strong economic assumptions and reliance on other studies' independent estimates to do the benchmarking. Due to the issues related with model-based estimates, historical WDI and ILO reports are collected to obtain survey-based estimates. The model-based estimates from ILO and WDI were used to update the share of self-employment when no other source of information is available.

Republic of Egypt, Equatorial Guinea, Eritrea, Ethiopia, Fiji, Gabon, The Gambia, Georgia, Ghana, Guinea, Guinea-Bissau, Guyana, Haiti, Islamic Republic of Iran, Jamaica, Jordan, Kenya, Kuwait, Kyrgyz Republic, Lao People's Democratic Republic, Latvia, Lebanon, Libya, Lithuania, Malawi, Maldives, Malta, Mauritania, Moldova, Morocco, Mozambique, Myanmar, Nepal, Niger, Nigeria, North Macedonia, Oman, Papua New Guinea, Qatar, Romania, Rwanda, Saudi Arabia, Senegal, Sierra Leone, Singapore, Solomon Islands, Sudan, Suriname, Swaziland, Syrian Arab Republic, Tajikistan, Tanzania, Togo, Trinidad and Tobago, Tunisia, United Arab Emirates, República Bolivariana de Venezuela, Vietnam, and Republic of Yemen.

Dating informal business cycles

Identifying turning points. Following Claessens, Kose, and Terrones (2012), Berge and Jorda (2011), and Harding and Pagan (2002), the Bry and Boschan (1971)'s algorithm is applied to date the business cycles of formal and informal sectors. Peaks (troughs) are defined as occurring at time t whenever $\{\Delta y_t > (<) 0, \Delta y_{t+1} < (>) 0\}$. As the censoring rule, if there are additional peaks/troughs within a 5-year period around a peak, the one with the deepest contraction/expansion is picked. When calculating characteristics of business cycles, the closest peaks (troughs) before troughs (peaks) are used when there are several peaks (troughs) in a row.

Characteristics of business cycle phases. The main characteristics of the recession and recovery phases, including duration, amplitude, and slope, are defined as in Claessens, Kose, and Terrones (2012):

- The *duration* captures, for a recession, the period from peak to trough and, for a recovery, the period it takes for output to return to its pre-trough peak.
- The *amplitude* of a recession measures the change in output from a peak to the next trough. The amplitude of a recovery measures the change in output during the first year of an expansion, which is the period between a trough and its following peak.
- The *slope* measures the speed of a given cyclical phase. It is defined as the ratio of amplitude over duration for a recession phase and the ratio of the change from the trough to the last peak divided by the duration for a recovery phase.

For recessions only, another widely used measure, cumulative loss, is calculated. It captures the overall cost of a recession. The cumulative loss is defined as the difference between the sum of annual changes in output and half of the amplitude during a recession.

TABLE 2.1.A Summary statistics

Estimation method	Aspect	Measures	# of obs	# of Econ.	Time period	Mean	Median	Min	Max

Note: Data for the period 1990-2018. DGE = dynamic general equilibrium model-based estimates of informal output in percent of official GDP; MIMIC = multiple indicators multiple causes model-based estimates on informal output in percent of GDP. World Values Survey (WVS) asks whether cheating on taxes is justifiable (1 is "never justifiable" and 10 is "always justifiable") and reports average responses at the country-year level, with a higher level suggesting that the country is more tolerant toward the informal sector. World Economic Forum (WEF) asks, "In your country, how much economic activity do you estimate to be undeclared or unregistered?" (1 = Most economic activity is undeclared or unregistered; 7 = Most economic activity is declared or registered) and reports average responses at the country-year level. Here, the average responses have been reordered to make "7 = Most economic activity is undeclared or unregistered; 1 = Most economic activity is declared or registered," where a higher level suggesting a larger informal sector in the country. WB shows the results for World Bank Enterprise Surveys. (a) stands for "Output" and (b) stands for "Opinions/Tax Morality." Since the data on self-employment for Equatorial Guinea is only for year 1989, the data on self-employment are available for 179 economies (instead of 180 economies) here.

EMDEs	3.84	5.90***	7.31***

Source: World Bank.

Note: Data are for the period 1990-2018. Formal output is captured by official GDP, while informal output uses dynamic general equilibrium (DGE)-based or multiple indicators multiple causes model (MIMIC)-based estimates. Total employment is the sum of formal employment and self-employment. Volatility shows the standard deviations (SDs) of the concerning variables' annual growth rates. *** implies significant differences at 1 percent level in the SDs of the annual growth rates of formal output and those of informal output in row [1]-[3] (in the SDs of the annual growth rates of total employment and those of formal/self-employment in row [4]-[6]). The shaded areas indicate that the SDs of the annual growth rates of DGE-based informal output (formal employment) significantly differ from those of MIMIC-based informal output (self-employment). ^ indicates significant differences at 5 percent level between advanced economies (AEs) and emerging market and developing economies (EMDEs).

Note: Data for recession episodes starting and ending in the period 1990-2018. Business cycle turning points determined based on formal and informal GDP levels (that is, official GDP statistics for formal output, dynamic general equilibrium (DGE)-based and multiple indicators multiple causes model (MIMIC)-based estimates for informal output) using the algorithm of Harding and Pagan (2002). Recession is defined as the phase from peak to trough while its corresponding "Duration," "Amplitude," "Cumulative loss," and "Slope" are defined as in Claessens, Kose, and Terrones (2012). All statistics correspond to sample means. Medians are in brackets. Asterisks refer to the significant differences in means (or medians) between advanced economies (AEs) and emerging market and developing economies (EMDEs). ***, **, * denote significance at the 1, 5, and 10 percent significance levels. Differences between informal and formal economies that are significant at 10 percent level are highlighted in shaded gray.

TABLE 2.5.B Cyclical features of recoveries in formal and informal economy

Formal Output				
	# of observations	Duration (years)	Amplitude (percent)	Slope (percent)
World	194	2.1 [1.5]	5.4 [3.3]	4.6 [2.1]
AEs	37	1.7 [2.0]	2.7** [2.3]**	2.0* [1.1]**
EMDEs	157	2.1 [1.6]	6.1 [3.6]	5.2 [2.4]
DGE-based Informal Output				
	# of observations	Duration (years)	Amplitude (percent)	Slope (percent)
World	236	2.0 [2.0]	4.1 [3.1]	3.6 [2.2]
AEs	58	1.9 [2.0]	2.4*** [1.8]***	2.2** [1.5]***
EMDEs	178	2.1 [2.0]	4.7 [3.7]	4.0 [2.5]
MIMIC-based Informal Output				
	# of observations	Duration (years)	Amplitude (percent)	Slope (percent)
World	87	1.6 [1.0]	3.5 [3.0]	2.3 [2.1]
AEs	22	1.5 [1.0]	1.9*** [1.7]***	1.4* [0.6]***
EMDEs	65	1.7 [1.0]	4.1 [3.4]	2.6 [2.1]

Source: World Bank.

Note: Data for recovery episodes starting and ending in 1990-2018. MIMIC = multiple indicators multiple causes model; DGE= dynamic general equilibrium model. Business cycle turning points determined based on formal and informal GDP levels (that is, official GDP statistics for formal output, DGE-based and MIMIC-based estimates for informal output) using the algorithm of Harding and Pagan (2002). Recovery is defined as the time it takes for output to rebound from the trough to the peak level before the recession while its corresponding "Duration," "Amplitude," and "Slope," are defined as in Claessens, Kose, and Terrones (2012). All statistics correspond to sample means. Medians are in brackets. Asterisks refer to the significant differences in means (or medians) between advanced economies (AEs) and emerging market and developing economies (EMDEs). ***, **, * denote significance at the 1, 5, and 10 percent significance levels. Differences between informal and formal economies that are significant at 10 percent level are highlighted in shaded gray.

TABLE 2.6.A Informal employment during formal and informal business cycles

	Formal output		DGE-based informal output		MIMIC-based informal output	
	Recession	Recovery	Recession	Recovery	Recession	Recovery
World	0.5 [1.1]	0.6 [0.3]	0.2 [0.7]	-0.4 [0.2]	-0.7 [0.5]	0.9 [0.1]
AEs	-0.7 [-0.2]**	-0.4 [0.03]	-0.6 [-0.3]*	-0.4 [-0.1]	-1.3 [-1.1]**	-0.3 [0.4]
EMDEs	1.3 [2.1]	1.1 [0.9]	0.8 [1.2]	-0.4 [0.2]	-0.3 [1.4]	1.5 [-0.9]

Source: World Bank.

Note: Data for the period 1990-2018. MIMIC = multiple indicators multiple causes model; DGE= dynamic general equilibrium model. Business cycle turning points determined based on formal and informal GDP levels (that is, official GDP statistics for formal output, DGE and MIMIC estimates for informal output) using the algorithm of Harding and Pagan (2002). Recession is defined as the phase from peak to trough while recovery is defined as the time it takes for output to rebound from the trough to the peak level before the recession (Claessens, Kose, and Terrones 2012). Expansion is defined as the period from trough to next peak (Claessens, Kose, and Terrones 2012). All statistics correspond to the sample means of the overall percentage changes in self-employment over the corresponding business cycle phases. Medians are in brackets. EMDEs with poor statistical capacity and three outliers (Democratic Republic of Congo, Gabon, and Zimbabwe) were dropped. Shaded cells represent numbers that significantly differ from zero. Asterisks refer to the significant differences in means (or medians) between advanced economies (AEs) and emerging market and developing economies (EMDEs). ***, **, * denote significance at the 1, 5, and 10 percent significance levels.

TABLE 2.6.B Formal and total employment during formal business cycles

	Total employment		Formal employment	
	Recession	Recovery	Recession	Recovery
World	-0.6 [-0.3]	1.3 [0.6]	-1.0 [-1.0]	1.5 [0.6]
AEs	-2.5*** [-1.4]***	-0.4** [-0.5]***	-2.7*** [-1.6]	-0.3** [-0.3]***
EMDEs	0.7 [1.2]	2.1 [1.6]	0.1 [-0.0]	2.5 [2.1]

Source: World Bank.

Note: Data for the period 1990-2018. Formal employment is proxied by total employment excluding self-employment. Business cycle turning points determined based on official GDP statistics for formal output using the algorithm of Harding and Pagan (2002). Recession is defined as the phase from peak to trough while recovery is defined as the time it takes for output to rebound from the trough to the peak level before the recession (Claessens, Kose, and Terrones 2012). All statistics correspond to the sample means of the overall percentage changes in total (formal) employment over the corresponding business cycle phases. EMDEs with poor statistical capacity and three outliers (Democratic Republic of Congo, Gabon, and Zimbabwe) were dropped. Medians are in brackets. Shaded cells represent numbers that significantly differ from zero. Asterisks refer to the significant differences in means (or medians) between advanced economies (AEs) and emerging market and developing economies (EMDEs). ***, **, * denote significance at the 1, 5, and 10 percent significance levels.

TABLE 2.7 Summary of data coverage

Data	Method	Sources	Measure	# of Ctry	Period	Setup
MIMIC-based informal output	Indirect estimates (MIMIC)	Author's calculations	Size of the informal sector as a percentage of official GDP estimated using the model of Schneider, Buehn, and Montenegro (2010).	160	1993-2018	Balanced panel
DGE-based informal output	Indirect estimates (DGE)	Author's calculations	Size of the informal economy as a percentage of official GDP estimated using the approach of Elgin and Oztunali (2012).	158	1950-2018	Balanced panel
Share of self-employment	Labor force survey and household survey	WDI, ILO, OECD, National Statistical Offices, Eurostat, IADB, Haver Analytics, and LSMS	The share of self-employment in total employment (survey-based estimates).	180	1955-2018	Unbalanced panel
Share of informal employment	Labor force survey and household survey	ILO	The share of informal employment in percent of total employment (harmonized)	72	2000-2018	Repeated cross-sections
Share of employment outside the formal sector	Labor force survey and household survey	ILO	The share of employment outside the formal sector in percent of total employment (harmonized).	76	1999-2018	Unbalanced panel
Pension coverage	Labor force survey and household survey	WDI	The fraction of the labor force that contributes to a retirement pension scheme.	135	1990-2010	Unbalanced panel
World Bank Enterprises Survey	Firm survey	World Bank Enterprise Survey	Four measures on informality: percent of firms competing against unregistered or informal firms, percent of firms formally registered when they started operations in the country, (average) number of years a firm operated without formal registration, and percent of firms identifying practices of competitors in the informal sector as a major constraint.	140	2006-2018	Repeated cross-sections

TABLE 2.7 Summary of data coverage (continued)

Data	Method	Sources	Measure	# of Econ.	Period	Setup
World Economic Forum (Executive Opinion Survey)	Firm survey	World Economic Forum	The extent of informal economy based on the question: "In your country, how much economic activity do you estimate to be undeclared or unregistered? (1 = Most economic activity is undeclared or unregistered; 7 = Most economic activity is declared or registered)."	154	2008-2018	Balanced panel dataset
Informal Market Index (Heritage Foundation)	Firm survey	Heritage Foundation	The subjective perceptions of general compliance with the law, with particular emphasis on the role played by official corruption. The index ranges from 1 to 5 with higher values indicating more informal market activity.	165	1995-2005	Balanced panel dataset
Non-observed activities (percent of GDP)	National account approach	UN (2008)	Non-observed activities (percent of GDP).	44	Various years	Cross-sectional data
The Eurobarometer Survey: Indirect measure of the informal economy	Household surveys and social opinion surveys	The Eurobarometer Survey	Interviewers ask respondents whether he/she has purchased goods or serviced embodied undeclared work or supplied labor in the informal economy. The survey also includes information on whether the respondents receive all or part of their regular salary or the remuneration for extra work or overtime hours as cash-in-hand and without declaring it to tax or social security authorities. Finally, the survey shows whether respondents find informal economic activities acceptable.	27	2007 and 2013	Repeated cross-sections
World Values Survey: Tax morale	Household surveys and social opinion surveys	World Values Survey	Interviewers ask whether respondents can justify cheating on taxes. Detailed descriptions are reported in table 2.9.	94	81-84, 94-98, 99-04, 05-09, 10-14	Repeated cross-sections
European Values Survey: Tax morale	Household surveys and social opinion surveys	European Values Survey	Interviewers ask whether it is justifiable for the respondents or their compatriots to cheat on taxes or pay cash to avoid taxes.	16-47	1981, 1990, 1999, and 2008	Repeated cross-sections
European Social Survey: Indirect measure of the informal economy	Household surveys and social opinion surveys	European Social Survey	Interviewers ask whether respondents paid cash for goods or services with no receipt so as to avoid VAT or taxes over the past five years and whether respondents have a written employment contract.	24	Every two years from 2004-2014	Repeated cross-sections

Source: World Bank.

Note: Absolute z-statistics in parentheses. ***, **, * denote significance at the 1, 5, and 10 percent significance levels. All variables are used as their standardized deviations from the mean. Data sources for variables used in the model are listed in Section II footnote 6. Following the MIMIC models' identification rule, the currency (M0/M1) variable is fixed to an a priori value. The currency variable shows the level of money (cash) in circulation. "AIC" = Akaike's information criterion; "BIC" = "Bayesian information criterion; "CD" = coefficient of determination; "CFI" = comparative fit index"; "RMSEA" = root mean square error of approximation; "TLI" = "Tucker Lewis index"; "SRMR" = "standardized root mean square residual." These are goodness-of-fit statistics.

TABLE 2.9 World Values Survey

Survey	Coverage
World Values Survey (WVS)	Questions: “Justifiable: cheating on taxes”. 1 is “never justifiable” and 10 is “always justifiable”
WVS 1981-1984	9 economies, such as: Argentina; Australia; Finland; Japan; Korea, Rep.; Mexico; South Africa; Sweden; United States.
WVS 1989-1993	16 economies, such as: Argentina; Brazil; Belarus; Chile; China; India; Japan; Korea, Rep.; Mexico; Nigeria; Poland; Russian Federation; South Africa; Spain; Switzerland; Turkey.
WVS 1994-1999	52 economies, such as: Albania; Argentina; Armenia; Australia; Azerbaijan; Bangladesh; Bosnia and Herzegovina; Belarus; Bulgaria; Chile; China; Colombia; Croatia; Czech Republic; Dominican Republic; El Salvador; Estonia; Finland; Georgia; Hungary; India; Japan; Korea, Rep.; Latvia; Lithuania; Mexico; Moldova; Montenegro; New Zealand; Nigeria; North Macedonia; Norway; Peru; Philippines; Poland; Puerto Rico; Romania; Russian Federation; Serbia; Slovak Republic; Slovenia; South Africa; Spain; Sweden; Switzerland; Ukraine; United States; Uruguay.
WVS 2000-2004	37 economies, such as: Albania; Algeria; Argentina; Bangladesh; Bosnia and Herzegovina; Canada; Chile; China; Egypt, Arab Rep.; India; Indonesia; Iran, Islamic Rep.; Japan; Jordan; Korea, Rep.; Kyrgyz Republic; Mexico; Moldova; Montenegro; Morocco; Nigeria; North Macedonia; Pakistan; Peru; Philippines; Puerto Rico; Serbia; Singapore; South Africa, Spain; Tanzania; Uganda; United States; Vietnam; Zimbabwe.
WVS 2005-2009	56 economies, such as: Andorra; Argentina; Australia; Brazil; Bulgaria; Burkina Faso; Canada; Chile; China; Colombia; Cyprus; Egypt, Arab Rep.; Ethiopia; Finland; France; Georgia; Germany; Ghana; Guatemala; Hungary; India; Indonesia; Iran, Islamic Rep.; Italy; Japan; Jordan; Korea, Rep.; Malaysia; Mali; Mexico; Moldova; Morocco; Netherlands; New Zealand; Norway; Poland; Romania; Russian Federation; Rwanda; Serbia; Slovenia; South Africa; Spain; Sweden; Switzerland; Thailand; Trinidad and Tobago; Turkey; Ukraine; United Kingdom; United States; Uruguay; Vietnam; Zambia.
WVS 2010-2014	57 economies, such as: Algeria; Argentina; Armenia; Australia; Azerbaijan; Brazil; Belarus; Chile; China; Colombia; Cyprus; Ecuador; Egypt, Arab Rep.; Estonia; Georgia; Ghana; India; Iraq; Japan; Kazakhstan; Jordan; Korea, Rep.; Kuwait; Kyrgyz Republic; Lebanon; Libya; Malaysia; Mexico; Morocco; Netherlands; New Zealand; Nigeria; Pakistan; Peru; Philippines; Poland; Romania; Russian Federation; Rwanda; Singapore; Slovenia; South Africa; Spain; Sweden; Thailand; Trinidad and Tobago; Tunisia; Turkey; Ukraine; United States; Uruguay; Uzbekistan; West Bank and Gaza; Yemen, Rep.; Zimbabwe.

CHAPTER 3

Growing Apart or Moving Together?

Synchronization of Informal- and Formal-Economy Business Cycles

Given its relative large size and the potential to dampen formal-economy business cycles, the informal economy needs to be factored into macroeconomic policy decisions. This chapter provides empirical evidence that informal output moves in the same direction as formal output, but in a more muted manner, with the direction of causality running from the formal economy to the informal economy. Informal employment, in contrast, does not co-move with the formal economy. Hence, the informal sector can provide a short-term buffer to formal-economy labor market disruptions even if, in the long run, it can act as a poverty trap. Policies that aim to curtail informal employment therefore need to be complemented with interventions that provide other buffers to short-term adverse shocks.

Introduction

In an average emerging market and developing economy (EMDE), the informal sector accounts for about one third of GDP, compared with about 18 percent of GDP in advanced economies (figure 3.1). Its large size makes the informal economy a potential amplifier or dampener of business cycles that policy makers need to take into account when deciding on countercyclical macroeconomic policies. If the informal economy expands while the formal economy contracts, it may support household incomes and consumer demand during economic downturns and serve as a safety net (Loayza and Rigolini 2011). If the informal economy behaves procyclically (that is, grows during expansions in the formal economy), it could function as an auxiliary “growth engine” during economic expansions (Chen 2005; Dell’Anno 2008; Meagher 2013).

In theory, the cyclical relationship between informal and formal sectors is ambiguous.¹ Some theoretical models have shown that the informal economy may absorb a larger share of workers as jobs become scarce in the formal sector during economic downturns (Bosch, Goni and Maloney 2007; Dix-Carneiro et al. 2021; Loayza and Rigolini 2011). Such behavior by the informal sector could facilitate economic recovery—by providing a potential supply of labor to the formal sector and preventing the hysteresis costs on unemployment—if re-entry into the formal sector is possible when the formal economy returns to expansion (Colombo, Onnis, and Tirelli 2016; IMF 2017).

In contrast, if informal firms provide services, as well as final and intermediate goods, to the formal sector, formal and informal sectors move in tandem. In addition, informal-

Note: This chapter was prepared by Ceyhun Elgin, M. Ayhan Kose, Franziska Ohnsorge, and Shu Yu. Research assistance was provided by Hrisyana Doytchinova and Maria Hazel Macadangdang.

¹ Some early research suggested that the degree of cyclicity of the informal economy depends on the measure of informality used and country characteristics.

economy income can support formal-economy demand. In these circumstances, the informal economy would amplify macroeconomic fluctuations.²

Empirical evidence on the behavior of the informal economy over the business cycle is also inconclusive. This has been attributed partly to different country characteristics and the roles of different economic shocks.

After presenting a brief review of the literature on the cyclical behavior of the informal economy, this chapter addresses the following questions:

- How synchronized are movements in informal and formal economies?
- Do fluctuations in formal economy output “cause” fluctuations in output or employment in the informal economy?

Contributions. The chapter makes three contributions to the literature. First, it is the first analysis of the cyclical relationships between formal and informal sectors using data for multiple measures of informality for a large set of economies—about 160 economies, comprising 36 advanced economies and about 120 emerging markets and developing economies (EMDEs). It covers a long, recent period—1990-2018—and is the first study of the behavior of both output and employment in the informal economy as previous studies have focused on either one of these two variables. The comparison yields valuable insights into the cyclical nature of labor productivity.

Second, the chapter focuses on the absolute size of the informal economy, while earlier studies examined the informal economy only in relation to the formal economy. This allows for a more precise understanding of cyclical dynamics. Earlier studies examined the size of the informal economy relative to that of the formal economy without explaining the underlying mechanism. For instance, when the relative size of the informal sector rises during recessions, it could reflect an expanding informal economy or an informal economy that shrinks less than the formal economy. Some previous studies have interpreted the rising ratio as evidence for an expanding informal economy during recessions. The few previous studies of the procyclicality of informal output levels have been restricted to a small group of countries and either study solely output (Bajada 2003; Dell’Anno 2008; Giles 1997) or solely employment (Fiess, Fugazza, and Maloney 2010).

Third, the chapter is the first to document a causal link from formal-economy cyclical developments to the informal economy by using an instrumental variables approach. This improves on existing studies that have tested for basic Granger causality between formal and informal economy within individual countries. The previous Granger causality tests help to determine whether one time-series is useful in forecasting another.

²For cyclical linkages between the formal sector and informal sector, see Arvin-Rad et al. (2010); Docquier, Muller, and Naval (2017); Gibson (2005); Lubell (1991); Roca, Moreno, and Sanchez (2001); Restrepo-Echavarría (2014); and Schneider (1998).

FIGURE 3.1 Formal and informal economy business cycles

Informal economic activity may amplify or dampen formal economy business cycles. In emerging market and developing economies (EMDEs), the shares of informal output and informal employment rise significantly above their long-term averages during formal economy downturns, even though informal output growth falls significantly below its long-term average. Informal employment growth remains around its long-term average during both upturns and downturns in the formal economy.

A. Share of informal economy

B. Changes in shares of informal economy during formal economy upturns and downturns in EMDEs

C. Output growth during formal economy upturns and downturns in EMDEs

D. Employment growth during formal economy upturns and downturns in EMDEs

Sources: Penn World Table 9.1; World Bank.

Note: Data are for 1990-2018. AEs = advanced economies; DGE = dynamic general equilibrium model estimates; EMDEs = emerging market and developing economies; FEMP = formal employment; LICs = low-income countries; MIMIC = multiple indicators and multiple causes model estimates; SEMP = self-employment. “Downturn” refers to growth rates of official GDP below zero, while “upturn” refers to growth rates of official GDP equal to or above zero. In B-D, *** indicates that the group average is significantly different from zero at the 10 percent level.

A. Bars show unweighted group averages for the latest year available, with the whiskers showing +/-1 standard deviation.

B. Shares of informal output (in percent of official GDP) and informal employment (in percent of total employment) are first-differenced and demeaned to capture detrended annual changes. Bars show unweighted group averages of detrended annual changes in shares of informal output/informal employment. Results for DGE-based estimates are shown in tenths.

C.D. Levels of output and employment in both formal and informal economies are logged, first-differenced and demeaned to capture detrended annual growth rates. Bars show unweighted group averages of detrended annual growth rates of output/employment levels.

However, they do not test for “true” causality as instrumental-variable regressions are able to identify (Angrist and Pischke 2009), since omitted variables can generate spurious causality (Eichler 2009).

Main Findings. The chapter reports two major results. First, informal-economy output moves in step with formal output: informal-economy output movements are strongly positively correlated with formal-economy output movements. Hence, when earlier

studies found that the share of the informal economy rose during formal-economy recessions, this reflected a slower absolute decline in informal than formal output rather than an absolute increase in informal activity. In addition, this chapter finds that informal employment largely behaves “acyclically.”

Second, in an instrumental variable estimation, the study shows that the direction of causality runs from the formal economy to the informal economy. Specifically, it documents a causal link from fluctuations in formal-economy output to fluctuations in informal-economy output. In terms of employment, such a causal link is not found: whereas informal output behaves procyclically, informal employment behaves acyclically. The latter may indicate that informal labor markets do not adjust in terms of employment status during economic cycles but in terms of wages or working hours (Guriev, Speciale, and Tuccio 2016; Meghir, Narita, and Robin 2015).

The rest of the chapter is organized as follows. First, the chapter summarizes past studies of the co-movement between formal and informal business cycles, followed by a section on the data and methodologies. The chapter then presents evidence on the co-movement of formal and informal economies. The chapter further provides new estimates of the causal relationship between formal and informal economy business cycles and discusses potential explanations for the cyclical behavior of the informal economy. Finally, it concludes with a discussion of policy implications and directions for future research.

Literature review: Linkages between formal and informal sectors

The literature on the cyclical behavior of the informal economy offers mixed conclusions. Studies focusing on the share of the informal economy in total output or employment tend to find countercyclical behavior whereas studies focusing on output or employment levels tend to find procyclical behavior. The theoretical literature suggests that the nature and degree of cyclicity will depend on the type of shocks causing business cycle fluctuations and on the presence of labor market rigidities. This section summarizes this literature.³

Informal economy as a countercyclical safety net

The informal sector can serve as a buffer and safety net for the poor if it absorbs labor during recessions. This can facilitate an economic recovery provided that re-entry into the formal sector is possible when the formal economy returns to expansion (Colombo, Onnis, and Tirelli 2016; IMF 2017; Loayza and Rigolini 2011).

³Several recent studies argue that pervasive informality may influence the measured cyclicity of the formal economy. For example, models with a large and poorly measured informal sector can generate excess volatility of formal consumption relative to formal output—a common feature of business cycles in many EMDEs (Horvath 2018; Restrepo-Echavarría 2014).

Macroeconomic evidence. Macroeconomic studies suggest that the informal economy can behave “countercyclically” in the sense that the share of informal employment rises during business cycle downturns. For example, one study reported that on average in 54 economies during 1984-2008, a one-standard-deviation slowdown in GDP per capita growth (that is a slowdown of 3 percentage points a year) was associated with a short-run increase in the share of self-employment in the total labor force by 1.2 percentage points, although with considerable cross-country heterogeneity (Loayza and Rigolini 2011).

In one study, the correlation between informal employment and official GDP has been estimated as modestly negative (about -0.3), whereas the correlation between formal employment and formal output was strongly positive (Fernández and Meza 2015). A study that used electricity consumption as a proxy for total economic activity found that the informal economy expanded following banking crises in 48 economies over the 1984-2005 period (Colombo, Onnis, and Tirelli 2016). Several studies have found that during economic downturns, the share of informal output tended to increase (Busato and Chiarini 2004; Elgin 2012; Kaufmann and Kaliberda 1996).

More procyclical fiscal policy in less developed economies with weaker institutions may contribute to the counter-cyclicality of informal activity. Fiscal policy tends to be more procyclical in countries with higher informality (Çiçek and Elgin 2011). In particular, procyclical fiscal consolidation during recessions, including through higher taxes, may encourage more informal employment and output.

Microeconomic evidence. Work-flow data for Brazilian metropolitan labor markets between 1983 and 2002 showed that the informal sector was able to absorb more labor during economic downturns as jobs became scarcer in the formal sector (Bosch, Goni, and Maloney 2007). The share of formal employment fell as formal-economy output contracted, in part because the rate at which workers found formal jobs plummeted while the rate at which they found informal jobs remained broadly stable (Bosch and Esteban-Pretel 2012).

Informal economy as a procyclical engine of growth

Since informal firms provide services, as well as final and intermediate goods to the formal sector, a positive correlation between formal and informal sector activity may emerge. In addition, informal-economy income can support formal-economy demand.⁴

Macroeconomic evidence. In studies focusing on absolute output levels rather than the share of the informal economy, movements in informal-economy output have been

⁴For linkages between the two sectors, see Arvin-Rad, Basu, and Willumsen (2010); Lubell (1991); and Moreno-Monroy, Pieters, and Erumban (2014). For linkages focusing on income support, see Docquier, Müller, and Naval (2017); Eilat and Zinnes (2002); Gibson (2005); Kanbur (2017); Schneider (1998); and World Bank (2014). Although the relationship between formal and informal sectors may be symbiotic in the short run, in the long-run pervasive informality may create poverty traps and stymie economic development.

found to be positively correlated with movements in formal-economy output in Australia, New Zealand, Canada, and a group of 19 Latin American economies (Bajada 2003; Dell'Anno 2008; Giles 1997; Tedds and Giles 2000). In a group of developing countries, episodes where relative demand or productivity shocks expanded the non-tradables sector (as opposed to the tradables sector) were associated with higher informal employment (hence, pro-cyclicality; Fiess, Fugazza, and Maloney 2010). In Brazil and Mexico, higher separation rates from informal jobs and a large drop of the formal job finding rate may induce labor outflows from the informal sector during recessions (Bosch and Maloney 2008). A theoretical model establishes procyclical informal-formal sector linkages when formal firms sub-contract labor-intensive stages of production to the informal sector (Arvin-Rad, Basu, and Willumsen 2010).

Microeconomic evidence. In firm-level data for India, formal and informal sector employment have been found to be positively correlated, in part because subcontracting by formal-sector firms to informal firms contributes to job creation in the informal sector (Moreno-Monroy, Pieters, and Erumban 2014).⁵ An examination of data from Indian manufacturing firms showed that the gross value added of several predominantly informal industries was positively correlated with that of the formal sector as well as with foreign direct investment (FDI). This may be indicative of technological spillovers to both formal and informal sectors (Beladi, Dutta, and Kar 2016).

Factors influencing the cyclicity of the informal economy

Some studies have sought to reconcile the mixed evidence by pointing to country characteristics that would generate different degrees of procyclicality. Others have pointed to different kinds of shocks that would lead to different types of cyclical linkages.

Cross-country heterogeneity. There is considerable cross-country heterogeneity in the degree of pro-cyclicality of informal employment. It has been found to be higher when informality was greater (Loayza and Rigolini 2011), when informal employment was more common (Shapiro 2014), or when there were stronger informal-formal sector linkages such as through subcontracting (Mbaye, Benjamin, and Gueye 2017; Moreno-Monroy, Pieters, and Erumban 2014).

Sources of shocks causing business cycles. The informal economy can move procyclically or countercyclically, depending on the sectoral origin of the shocks that generate business cycles in the presence of wage rigidities, especially in the formal sector (Fiess, Fugazza, and Maloney 2010; Leyva and Urrutia 2018). Positive relative demand or productivity shocks to the non-tradable sector, especially services, where the share of informal employment tends to be higher could increase informal employment,

⁵ In an earlier study focusing on two European countries, it was found that at least two-thirds of the income earned in the informal economy was immediately spent in the formal economy, providing a considerable stimulus for it (Schneider 1998).

generating procyclicality in informal employment, especially when combined with wage rigidities in the formal sector.⁶ Conversely, in the presence of wage rigidities, a negative shock to the tradable sector would expand informal (non-tradables) employment and thus appear as countercyclical.

Data and methodology

This chapter relies on the database developed in the previous chapter. It applies a battery of statistical tests to establish, first, co-movement between formal output and measures of informal activity and, second, to analyze the direction of causality.

Data. This chapter uses the two model-based estimates of informal output—the multiple indicators multiple causes (MIMIC) estimates and the dynamic general equilibrium (DGE) estimates (chapter 2).⁷ Annual MIMIC estimates are available for 160 economies (including 36 advanced economies) for 1993–2018. Annual DGE estimates are available for 158 economies (including 36 advanced economies) for 1990–2018. These measures of informal output are complemented with self-employment as a proxy indicator of informal employment (La Porta and Shleifer 2014). Annual data on shares of self-employment are available for 179 economies (including 36 advanced economies) between 1990 and 2018. All measures of informal activity are defined in levels of output or levels of employment, rather than as shares of total activity or employment as is standard practice in the business cycle literature (for example, Claessens, Kose, and Terrones 2012; Fernández and Meza 2015). Data for formal output are from the Penn World Table 9.1 and the World Development Indicators (WDI) (in 2011 U.S. dollars; data from Penn World Table 9.1 were expanded using WDI). The Hodrick-Prescott (HP) filter is used to detrend the time series with the smoothing parameter set to 100. All exercises rely on detrended logarithms of these levels. The findings are robust to using annual growth of formal and informal output and employment or to using the Baxter-King filter to detrend series.

Methodologies. To quantify the co-movement of formal output with the various measures of informality, the chapter employs a wide range of measures, including correlation, factor models, coincidence of turning points and business cycle phases, and probit and linear regression models (Claessens, Kose, and Terrones 2012; Kose, Prasad, and Terrones 2003; Restrepo-Echevarria 2014). Some methodological details are presented in annex 3B. As a second step, the chapter uses a two-stage least squares instrumental variable approach to estimate the direction of causality between formal output and measures of informal activity. Specifically, formal-economy output is instrumented using government consumption, export growth, and trade-to-GDP ratios. The methodology is described in greater detail in annex 3C.

⁶ See chapter 4 for a discussion about sectoral distribution in the informal economy. Informality tends to be higher in labor-intensive service sectors, which are largely non-tradable.

⁷ The correlation of the DGE measure does not occur by construction (see annex 3A for details).

FIGURE 3.2 Correlations of informal output with formal output

Informal-economy output is highly and positively correlated with formal-economy output, both contemporaneously and in lagged terms. Formal employment is also positively and significantly correlated with formal-economy output, whereas informal employment is largely uncorrelated with formal-economy output in emerging market and developing economies (EMDEs).

A. Correlation between formal output and informal output (DGE-based estimates)

B. Correlation between formal output and informal output (MIMIC-based estimates)

C. Correlation between formal output and formal employment

D. Correlation between formal output and informal employment

Sources: Penn World Table 9.1; World Bank.

Note: Data are for 1990-2018. AEs = advanced economies; EMDEs = emerging market and developing economies. DGE = dynamic general equilibrium model estimates, MIMIC = multiple indicators and multiple causes model estimates. *** denotes 10 percent significance.

A.-D. Each bars shows the correlation between the cyclical components of formal-economy output (in logs, of year $t(-2)$, $t(-1)$ and $t(0)$) and the cyclical components of informal-economy output (A, B; in logs), formal employment (that is, total employment excl. self-employment in logs; in C) and informal employment proxied by self-employment (in D; in logs) of year $t(0)$.

Synchronization of formal and informal business cycles

A battery of statistical exercises suggests that informal output is strongly positively correlated with formal output, hence behaves in a procyclical manner. In contrast, informal employment is largely unrelated to formal output movements, hence behaves in an acyclical manner.

Correlations. Contemporaneously, informal-economy output movements are highly and statistically significantly correlated with formal-economy output movements (figure 3.2). Formal employment is also positively and statistically significantly correlated with

FIGURE 3.3 Co-movement between formal and informal business cycles

A common factor explains about 40 percent of variance in formal-economy output. It also explains 40 percent of variance of informal-economy output when based on DGE estimates, and 24 percent using MIMIC estimates. However, it only explains about 10 percent or less of movements in formal employment and informal employment.

A. Share of variance in formal output and informal output explained by a common factor

B. Share of variance in formal output and formal and informal employment explained by a common factor

Sources: Penn World Table 9.1; World Bank.

Note: Data are for 1990-2018. All data series are transformed into cyclical components and standardized before the estimations. AEs = advanced economies; DGE = dynamic general equilibrium model estimates; EMDEs = emerging market and developing economies; MIMIC = multiple indicators and multiple causes model estimates. Formal employment is proxied by total employment excluding self-employment. Informal employment is proxied by self-employment.

A.B. Bars show the median (diamond for mean) fractions of variance explained by the common dynamic factor in each group. The results here are obtained from estimating dynamic common factor model, as in Stock and Watson (2011), for each country in the sample (see annex 3B for details). AR(1) process for the common dynamic factor is used, as suggested by the estimation results.

formal-economy output, although considerably less strongly, particularly in EMDEs, whereas informal employment is largely uncorrelated with formal-economy output, again particularly in EMDEs. Lag correlations are considerably smaller than contemporaneous correlations, suggesting that informal output responds to formal-economy output fluctuations within a year.⁸

Common factor approach. For each country, a common factor is extracted from informal- and formal-sector output as well as informal and formal employment, in a dynamic factor model (annex 3B; Kose, Prasad, and Terrones 2003). The results are broadly in line with the correlations discussed above. On average, the common factor explains about 40 percent of the variance in both formal-economy output and DGE-based informal-economy output (figure 3.3). It explains somewhat less (24 percent) of the variance in MIMIC-based informal-economy output, in part because MIMIC estimates tend to be more stable than DGE estimates as a result of the reliance of the former measure on slow-moving country characteristics such as economic and business freedom indices. The common factor also explains a modest fraction of movements in formal employment, especially in advanced economies. In contrast, informal

⁸ In EMDEs, however, lag correlations are statistically indistinguishable from contemporaneous correlations.

FIGURE 3.4 Coincidence of formal and informal business cycles

In more than 90 percent of country-year pairs, formal and informal output are in the same business cycle phase. This coincidence of business cycle phases is less pronounced for employment than for output, with informal employment being in the same phase as formal output in about a half of country-year pairs.

A. Coincidence of business cycle phases: Formal and informal output

B. Coincidence of business cycle phases: Formal output and employment

C. Coincidence of business cycle turning points: Formal and informal output

D. Coincidence of business cycle turning points: Formal output and employment

Sources: Penn World Table 9.1; World Bank.

Note: Data are for 1990-2018. Business phases and turning points are identified as in chapter 1. Recessions are the periods from peak to trough, while expansions are the periods from trough to peak (Claessens, Kose, and Terrones 2012). Trough and peaks are identified as in chapter 1, where the Bry and Boschan (1971) method is used to identify turning points.

DGE = dynamic general equilibrium model estimates; MIMIC = multiple indicators and multiple causes model estimates. Formal employment is proxied by total employment excluding self-employment. Informal employment is proxied by self-employment.

A.B. Bars show the percent of country-year pairs where formal output and informal output (in A; formal or informality employment in B) are in the same business cycle phases (that is, both are in recession, or in expansions, or in either cases, labelled as "both").

C.D. Bars show the share of formal peaks (or troughs) that happen to be informal peaks (or troughs).

employment does not appear to share a common factor with formal employment or with informal or formal-economy output in either advanced economies or EMDEs.

Coherence in business cycle phases and turning points. Formal- and informal-sectors typically share the same business cycle phases (figure 3.4). In more than 90 percent of country-year pairs, formal and informal output are in the same business cycle phase. This coincidence of business cycle phases is considerably less pronounced for employment than for output. Formal employment and formal output share the same business cycle phases in 75 percent of all country-year pairs, while informal employment is in the same phase as formal output in 54 percent of country-year pairs. Similarly,

between 30 and 70 percent (using MIMIC or DGE, respectively) of turning points (peak or trough) of formal output business cycles coincide with turning points of informal output business cycles, whereas informal employment turning points coincide about 10 percent of the time with formal-economy output turning points.

Econometric approaches. A probit regression is used to estimate the probability of the informal economy being in recession at the same time as the formal economy is (annex 3B). Indeed, the probability of informal output being in recession is statistically significantly higher when formal output is in a recession, even after controlling for country and year fixed effects as well as investment and credit growth (figure 3.5). On average, the probability of informal output being in recession is higher by about 25 percentage points when formal output is in recession than when formal output is not in recession.⁹ Similar results pertain to the probability of a new recession starting in the informal sector when the formal economy is in recession. Again, this contrasts with the finding that the probability of informal employment declining is little affected by a formal-economy contraction.

Causal linkages between formal- and informal-economy business cycles

The results described in the previous section suggest a strong correlation between formal and informal economies. Some previous studies reported strong evidence of Granger causality running from the formal economy to the informal economy in individual countries, and mild evidence of reverse causality in some cases (Bajada 2003; Giles 1997; Giles, Tedds, and Werkneh 2002). However, Granger causality does not establish “true” causality and ignoring reverse causality could lead to biased estimation results (Angrist and Pischke 2009). Hence, the chapter employs a novel approach with an instrumental variables estimation to test for the direction of causality. The results based on this approach suggest that formal economy output fluctuations “truly” cause informal-economy output fluctuations.

Econometric approach. Formal-economy output is instrumented using government spending and two trade-related variables: the cyclical components of the terms of trade and real exports (annex 3C). Being largely concentrated in the non-tradable sector, the informal economy is unlikely to be highly influenced directly by movements in trade-related variables. In addition, government spending is typically restricted, by legislation and regulation, from purchasing goods and services from the informal economy. Therefore, movements in trade-related variables and changes in government consumption can be interpreted as exogenous instruments that directly affect the formal economy without directly influencing the informal economy.

⁹ Probabilities for the global sample need not be near the average of the advanced economy and EMDE sample because of different year fixed effects.

FIGURE 3.5 Probability of a recession

Informal output and formal employment are more likely to be in (or moving toward) a recession when formal output is in a recession. However, the same does not hold for informal employment.

A. Impact of formal output recession on probability of informal output recession

B. Impact of formal output recession on probability of employment recession

C. Impact of formal output recession on probability of starting an informal output recession

D. Impact of formal output recession on probability of starting an employment recession

Source: World Bank.

Note: Data are for 1990-2018. Average marginal effects are shown in bars. Recessions are the periods from peak to trough, while expansions are the periods from trough to peak (Claessens, Kose, and Terrones 2012). Trough and peaks are identified as in chapter 1, where the Bry and Boschan 1971 method is used to identify turning points. AEs = advanced economies; DGE = dynamic general equilibrium model estimates; EMDEs = emerging market and developing economies; MIMIC = multiple indicators and multiple causes model estimates. Formal employment is proxied by total employment excluding self-employment. Informal employment is proxied by self-employment. *** denotes 10 percent significance.

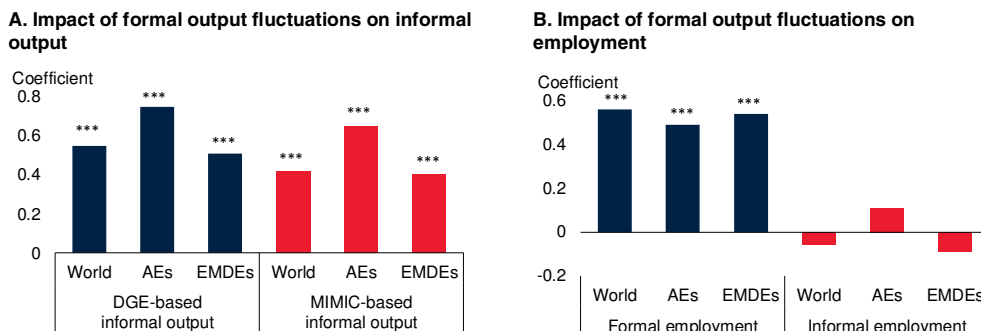

A.B. Bars show regression results from the following probit model: $Pr(ISREC_{it} + 1) = \phi(\alpha + \beta FS_{it} + \theta X_{it} + \pi_i + \mu_t + \epsilon_{it})$, where $ISREC_{it}$ is a dummy variable that equals one when the informal sector in country i and year t is in recession, and zero otherwise. FS_{it} is a dummy representing recession in the formal economy, and X_{it} is a vector of control variables (including the annual growth rates of real investment and domestic credit to the private sector; PWT 9.1 and 2020 World Development Indicators). All regressions include country dummies (π_i) and year dummies (μ_t). See annex 3B for details.

C.D. Bars show regression results from the probit model with the same form as in A and B. Here $ISREC_{it}$ is a dummy variable that equals one when the informal sector in country i and year t is in the start of a recession, and zero otherwise. See annex 3B for details.

Results. The regression results confirm that formal-economy output fluctuations in the previous year, as instrumented by lagged trade-related terms and government consumption, “cause” fluctuations in the informal economy in the following year. On average, a 1 percent increase in formal-economy output “causes” a 0.4-0.8 percent expansion in the following year in informal-economy output and formal employment. This impact does not differ materially between advanced economies and EMDEs. In contrast, such formal-economy output fluctuations do not cause significant fluctuations in informal employment, especially in EMDEs (figure 3.6).

FIGURE 3.6 Impact of formal output fluctuations on the informal sector

A 1 percent increase in formal economy output raises informal output and formal employment by 0.4-0.8 percent one year later, but does not affect informal employment significantly.

Source: World Bank.

Note: Data are for 1990-2018. See annex 3C for details. Government consumption and trade-related terms (proxied by terms of trade and exports) are included as instrumental variables (IVs) to explain the variation in formal output (proxied by official GDP). AEs = advanced economies; DGE = dynamic general equilibrium model estimates; EMDEs = emerging market and developing economies; MIMIC = multiple indicators and multiple causes model estimates. Formal employment is proxied by total employment excluding self-employment. Informal employment is proxied by self-employment. *** denotes 10 percent significance.

A. Bars show estimated coefficients when DGE- or MIMIC-based estimates are used as the dependent variable.

B. Bars show estimated coefficients when formal employment or informal employment (defined as self-employment) are used as the dependent variable.

Robustness tests. These results are robust to several alternative specifications. Instrumenting only with either trade-related variables or government consumption yields similar results. In addition, the results are robust to using system Generalized Methods of Moments (GMM) estimation to address potential endogeneity; to specifying the dependent variable in terms of the share of the informal economy in the total economy (annex 3C); and to using an alternative variant of the DGE measures to test for robustness to different modelling assumptions in the construction of the DGE estimates (annex 3D).

Explaining the cyclicity of the informal sector

The previous sections have established that informal-economy output and formal employment behave “procyclically,” in the sense of responding to formal-economy output fluctuations significantly and positively. Meanwhile, informal employment acts “acyclically” in the sense of not significantly and systematically responding to formal-economy output fluctuations. This accounts for the rising share of informal employment during formal-economy recessions documented by studies like Loayza and Rigolini (2011).

There are at least two possible reasons explaining why informal employment behaves acyclically. First, informal employment may respond to different shocks from informal output and formal employment, or it may respond differently to the same shocks. As an example of the latter, the informal labor market, being more flexible than the formal

sector, may respond by reducing hours worked per person or by lowering wages, rather than by reducing the number of employed.¹⁰ A second possible reason is that while job separation rates rise during recessions in both formal and informal sectors, the rate at which workers find formal jobs plummets while that at which they find informal jobs remains broadly stable (Bosch and Esteban-Pretel 2012; Bosch, Goni, and Maloney 2007).

Conclusion

This chapter presents a wide variety of approaches that document the strong co-movement of informal-economy output with formal-economy output, caused by movements in formal output, but the lack of such co-movement for informal employment. This suggests that although output in the informal economy behaves procyclically and, therefore, may amplify aggregate output fluctuations (for example, Ferreira Tiryaki 2008; Roca, Moreno, and Sánchez 2001), the unresponsiveness of informal employment to the business cycle may provide a buffer for household incomes by ensuring continuity of employment in the informal economy.

The resilience of informal employment in the face of business cycle swings, juxtaposed with the weaker development levels associated with informality (discussed in chapter 4), suggests a trade-off. In the short run, informal employment can provide a safety net during business cycles; in the long term, however, the informal sector can exacerbate poverty and stymie development (Docquier, Müller, and Naval 2017). Policy measures that—deliberately or inadvertently—reduce informality and thus benefit longer-term development and poverty reduction could, therefore, usefully be accompanied by a strengthening of official social safety nets to protect vulnerable population groups from the short-term costs of the loss of the unofficial safety net provided by the informal sector. The necessity of strengthening the resilience of the informal sector is particularly relevant in the context of the COVID-19-induced recession (box 2.1).

Also, if co-movement between formal and informal output reflects synergies, such as through subcontracting, policy measures aimed at curtailing informal activity could disrupt formal activity. These effects could be mitigated if measures that reduce informality were accompanied by greater labor and product market flexibility in the formal sector that facilitates the absorption of informal participants (World Bank 2019).

Directions for future research. The results reported in this chapter point to several promising areas for future research. First, the cyclical behavior of other features of the informal economy could usefully be examined. For example, if greater flexibility of wages or hours worked is what ensures acyclical behavior of informal employment despite procyclical informal output, then informal wages or hours of employment should be particularly procyclical. It would be useful to establish whether this is the case.

¹⁰ For discussions of these arguments, see Guriev, Speciale, and Tuccio (2016); Loayza and Rigolini (2011); Maloney (2004); and Meghir, Narita, and Robin (2015).

Second, the channels through which formal-economy business cycles affect the informal economy could be further explored and quantified. This includes the degree of interconnectedness between formal and informal firms.

ANNEX 3A Theory behind the cyclicity of the Dynamic General Equilibrium (DGE)-based estimates

The production function for official GDP is assumed to have the following form:

$$Y_{Ft} = A_{Ft} K_t^\alpha N_{Ft}^{1-\alpha}$$

where Y_{Ft} is output in the formal sector in year t , A_{Ft} is total factor productivity in the formal sector in year t , K_t is the capital stock available in year t , and N_{Ft} is employment in the formal sector in year t .

The production function for informal output is assumed to have the following form:

$$Y_{It} = A_{It} N_{It}^\gamma,$$

where Y_{It} is output in the informal sector in year t , A_{It} is labor productivity in the informal sector, and N_{It} is employment in the informal sector. As assumed in Elgin and Oztunali (2012), $\hat{A}_{It} = 1/2 (\hat{K}_t + \hat{A}_{Ft})$ and N_{It} is a function of A_{Ft} and K_t . To simplify the discussion, it is assumed that $A_{It} = 1/2 (A_{Ft} + K_t) + c$, where c is a constant. N_{It} has the following form:¹¹

$$N_{It} = \left\{ \frac{\gamma A_{It}}{(1-\tau_t)(1-\alpha)A_{Ft}} \left[\frac{\frac{1}{\beta} - 1 + \delta}{\alpha(1-\tau_t)A_{Ft}} \right]^{\frac{\alpha}{1-\alpha}} \right\}^{\frac{1}{1-\gamma}}$$

Since A_{It} and N_{It} are functions of A_{Ft} and K_t , Y_{It} can be expressed as a function of A_{Ft} and K_t . The co-movement between Y_{It} and Y_{Ft} can be only driven by shocks in A_{Ft} and K_t . Assuming that shocks in N_{Ft} are not related to shocks in K_t nor in A_{Ft} , since $\frac{\partial Y_{Ft}}{\partial K_t} > 0$ and $\frac{\partial Y_{Ft}}{\partial A_{Ft}} > 0$, the positive correlation between Y_{Ft} and Y_{It} could be driven by construction if $\frac{\partial Y_{It}}{\partial A_{Ft}} > 0$ and $\frac{\partial Y_{It}}{\partial K_t} > 0$. Therefore, the values of $\frac{\partial Y_{It}}{\partial A_{Ft}}$ and $\frac{\partial Y_{It}}{\partial K_t}$ will be discussed below.

First, $\frac{\partial Y_{It}}{\partial K_t} = N_{It}^\gamma \frac{\partial A_{It}}{\partial K_t} + A_{It} * \gamma N_{It}^{\gamma-1} * \frac{\partial N_{It}}{\partial K_t}$, where $\frac{\partial N_{It}}{\partial K_t} > 0$ and $\frac{\partial A_{It}}{\partial K_t} = \frac{1}{2} > 0$.

Hence, $\frac{\partial Y_{It}}{\partial K_t} > 0$.

¹¹ See Elgin and Oztunali (2012) for the definitions of the parameters used here.

Second, it is easy to derive that

$$\frac{\partial Y_{It}}{\partial A_{Ft}} = N_{It}^{\gamma} \frac{\partial A_{It}}{\partial A_{Ft}} + A_{It} * \gamma N_{It}^{\gamma-1} * \frac{\partial N_{It}}{\partial A_{Ft}} = N_{It}^{\gamma} \left(\frac{1}{2} + \gamma * \frac{A_{It}}{N_{It}} * \frac{\partial N_{It}}{\partial A_{Ft}} \right)$$

where
$$\frac{\partial N_{It}}{\partial A_{Ft}} = \Omega * A_{It}^{\frac{\gamma}{1-\gamma}} (A_{Ft})^{\frac{1}{-(1-\alpha)(1-\gamma)}} * \frac{1}{1-\gamma} * \left[\frac{1}{2} - \frac{1}{1-\alpha} * \frac{A_{It}}{A_{Ft}} \right]$$

and
$$\Omega = \left\{ \frac{\gamma}{(1-\tau_t)(1-\alpha)} \left[\frac{\frac{1}{\beta} - 1 + \delta}{\alpha(1-\tau_t)} \right]^{\frac{\alpha}{1-\alpha}} \right\}^{\frac{1}{1-\gamma}}$$

Since $\alpha = 0.36$ and $A_{It} = 1/2 (A_{Ft} + K_t) + c$, $\frac{1}{2} - \frac{1}{(1-\alpha)} * \frac{A_{It}}{A_{Ft}} < 0$ and $\frac{\partial N_{It}}{\partial A_{Ft}} < 0$.

This yields
$$\frac{\partial Y_{It}}{\partial A_{Ft}} = N_{It}^{\gamma} * \left[\frac{1}{2} + \frac{\gamma}{1-\gamma} * \left(\frac{1}{2} - \frac{1}{(1-\alpha)} * \frac{A_{It}}{A_{Ft}} \right) \right]$$

Hence, if $\frac{A_{It}}{A_{Ft}}$ falls below $\frac{1-\alpha}{2\gamma} \approx 0.75$, $\frac{\partial Y_{It}}{\partial A_{Ft}}$ turns from positive to negative.

Since the co-movement between Y_{It} and Y_{Ft} are largely driven by the assumption that $\dot{A}_{It} = 1/2(\dot{K}_t + \dot{A}_{Ft})$, the DGE model is re-estimated by benchmarking N_{It} to survey-based self-employment in annex 3D as a robustness check. This gives the estimates of A_{It} and subsequently Y_{It} without relying on specific assumption. The regression results for IV-2SLS models using DGE estimates benchmarked to self-employment are largely in line with those shown in the main text.

ANNEX 3B Model specifications for measuring co-movement among informality measures

Dynamic common factor model

The dynamic common factor model has the following form (Stock and Watson 2011):

$$Y_t = \beta f_t + \varepsilon_t; f_t = \phi(L)f_{t-1} + \mu_t,$$

where Y_t is a vector of variables that contains official GDP, DGE-based and MIMIC-based informal output estimates, formal employment, and informal employment. f_t is the dynamic common factor, which follows an AR(1) process. ε_t and μ_t are error terms (i.d.d.). The dynamic common factor model is estimated for each country. Robustness tests for longer lags indicate that the coefficients for additional lags of the common factor

are insignificant. All data series are detrended and standardized before estimation. Additional results are available upon request.

Probit model

The probit model has the following form:

$$Pr(ISREC_{it} = 1) = \Phi(\alpha + \beta FS_{it} + \theta X_{it} + \pi_i + \mu_t + \epsilon_{it}),$$

where $ISREC_{it}$ is a dummy variable that equals one when the informal sector in country i and year t is in recession, and zero otherwise. FS_{it} is a dummy representing recession in the formal economy, and X_{it} is a vector of control variables. Following Elgin and Oztunali (2012 and 2014), X_{it} includes the annual growth rates of real investment (Penn World Table 9.1) and domestic credit to the private sector obtained from World Development Indicators. All regressions include country dummies (π_i) and year dummies (μ_t) to control for macro trends across countries in a certain year and factors that are country specific. For probit model on the start of informal recessions, $ISREC_{it}$ is a dummy variable that equals one when the informal sector in country i and year t is in the start of a recession, and zero otherwise. Recessions are identified as in chapter 1, where Bry and Boschan 1971 algorithm is used to identify peaks and troughs of business cycles and recessions are defined as the period from peak to trough (Claessens, Kose, and Terrones 2012).

ANNEX 3C Causal linkages between formal- and informal- economy business cycles

The following instrumental variables that affect formal-economy output but do not directly influence informal-economy output are considered: movements in trade-related variables and changes in government consumption. Being concentrated in the non-tradable sector (Fiess, Fugazza, and Maloney 2010), the informal economy is unlikely to be influenced by movements in trade-related variables directly. In addition, government consumption includes all government current expenditures for purchases of goods and services (including compensation of employees), without covering transfers such as social benefits, subsidies and so on. Governments are typically restricted, by legislation and regulation, from purchasing goods and services directly from the informal economy. As governments purchase goods and services from the formal economy, changes in government consumption lead to fluctuations in the formal economy without affecting the informal economy directly. Therefore, movements in trade-related variables and changes in government consumption can be interpreted as exogenous instruments that directly affect the formal economy without directly influencing the informal economy.

Data on movements in trade-related variables and changes in government consumption are obtained from WDI. Trade-related variables include terms of trade and exports of goods and services (at constant 2010 U.S. dollars). Government consumption captures general government final consumption expenditure (at constant 2010 U.S. dollars).

These measures—as well as all the output and employment measures—are transformed into cyclical components as deviations from the Hodrick-Prescott-filtered trend with a smoothing parameter of 100. To further make sure that the causal direction only runs from the formal economy to the informal economy, cyclical movements in formal GDP are lagged in the following regressions. The results are robust to using annual growth rates of these variables and when cyclical movements in formal GDP are not lagged.

The IV-2SLS regression model has the following form:

$$FS_{it-1} = \alpha_1 + IV_{it-1} + \mathbf{0}X_{it} + \pi_i + \mu_t + \epsilon_{it} \quad (1^{st} \text{ Stage})$$

$$IS_{it} = \alpha_0 + \beta \widehat{FS}_{it-1} + \mathbf{0}X_{it} + \pi_i + \mu_t + \epsilon_{it} \quad (2^{nd} \text{ Stage})$$

In the first stage, the lagged cyclical component of formal-economy output (FS_{it-1}) is the dependent variable, while the lagged trade-related variables and government consumption in country i (IV_{it-1}) are the explanatory variables. The regression results of the first stage are used to obtain the estimated cyclical component of formal economy output \widehat{FS}_{it-1} , which is used as the explanatory variable in the 2nd stage. \widehat{FS}_{it-1} is used to explain the cyclical components of informal-economy output or informal employment (IS_{it}) in year t . The coefficient estimates β measures the magnitude and direction of the impact of fluctuations in the formal business cycle on the informal economy. In both stages, a vector of control variables (X_{it}), country fixed effects (π_i) and year fixed effects (μ_t) are controlled for. The vector of control variables (X_{it}) includes the growth rates of domestic credit to the private sector and real investment. These control variables are included as they influence the fluctuations in both formal and informal economies (for example, Elgin and Oztunali, 2014; Ferreira Tiyaki 2008; La Porta and Shleifer 2014). Data for investment are provided by PWT 9.1, updated with data from WDI, and credit data are obtained from WDI. Detailed baseline estimation results are shown in table 3.1.

Movements in trade-related terms and changes in government consumption are jointly used as instruments for formal-economy output fluctuations. To remove the potential endogeneity of government consumption in the case of MIMIC, results are also obtained using trade-related instrumental variables (terms of trade and export growth) only (figure 3C.1).

Several robustness exercises are carried out. First, system GMM is carried out to address potential endogeneity bias. The results are strongly in line with baseline findings, where a 1 percent rise in formal economy output significantly increases output in the informal sector in the following year by 0.4-0.8 percent but no significant response from informal employment (figure 3C.2). Second, an alternative variant of the DGE measures, detailed in methodological annex 3D, is used to test for robustness to different modelling assumptions in the construction of the DGE estimates. The results show that on average, informal output expands significantly by 0.5-0.8 percent, especially in EMDEs, when formal-economy output rises by 1 percent in the previous year. Third, the same set

FIGURE 3C.1 Impact of formal output fluctuations on the informal sector: Alternative instrumental variables

Results from using alternative sets of instrumental variables, such as trade-related variables or government consumption alone, confirm baseline results that expansion in formal-economy output significantly leads to a rise in informal output in the following year, while having no significant impact on informal employment.

A. Impact of formal output fluctuations on informal output: Trade-related variables

B. Impact of formal output fluctuations on employment: Trade-related variables

C. Impact of formal output fluctuations on informal output: Government consumption

D. Impact of formal output fluctuations on employment: Government consumption

Source: World Bank.

Note: Data are for 1990-2018. Trade-related variables (proxied by terms of trade and export) are used as the instrumental variable to explain the variation in formal output (proxied by official GDP) in A and B, while government consumption is used as the instrumental variable in C and D. See annex 3C for details. AEs = advanced economies; DGE = dynamic general equilibrium model estimates; EMDEs = emerging market and developing economies; MIMIC = multiple indicators and multiple causes model estimates. Formal employment is proxied by total employment excluding self-employment. Informal employment is proxied by self-employment. *** denotes 10 percent significance.

A.C. Bars show estimated coefficients when DGE- or MIMIC-based estimates are used as the dependent variable.

B.D. Bars show estimated coefficients when formal employment or informal employment (defined as self-employment) are used as the dependent variable.

of empirical analyses are applied to the shares of the informal economy in output and employment to ensure consistency with previous estimates in the literature. Both correlation and IV-2SLS regression analyses are carried out here. As expected, both shares of informal output and shares of informal employment are found to be significantly negatively correlated with formal-economy output, while shares of formal employment are positively correlated (figure 3C.3). The regression results show that the share of informal output contracts significantly by 0.1-0.4 percentage points of GDP, on average, when formal-economy output expands by 1 percent in the previous year (figure 3C.4).

FIGURE 3C.2 Impact of formal output fluctuations on the informal sector: Additional robustness checks

Robustness checks, such as ones using a fixed-effect estimator and a system generalized methods of moments (GMM) estimator, confirm formal findings that rises in formal-economy output significantly increase output in the informal sector in the following year while having no significant impact on informal employment.

A. Impact of formal output fluctuations on informal output (DGE-based estimates)

B. Impact of formal output fluctuations on informal output (MIMIC-based estimates)

C. Impact of formal output fluctuations on formal employment

D. Impact of formal output fluctuations on informal employment

Source: World Bank.

Note: Data are for 1990-2018. *** denotes 10 percent significance. AEs = advanced economies; DGE = dynamic general equilibrium model estimates; EMDEs = emerging market and developing economies; MIMIC = multiple indicators and multiple causes model estimates. Formal employment is proxied by total employment excluding self-employment. Informal employment is proxied by self-employment. See annex 3D for details on "alternative DGE-based estimates". "Fixed effects" show results for the fixed-effect model, where the dependent variable is the cyclical component of informal output or employment derived using the Hodrick-Prescott-filter, and the variable of interest is the lagged Hodrick-Prescott-filtered(HP) cyclical component of official GDP. Country fixed effects and year dummies are used here. "System GMM" shows regression results from system generalized methods of moments (GMM) estimators with informal output, formal employment and informal employment being the dependent variables and lagged official GDP being the explanatory variable. All dependent variables and official GDP are cyclical components (in logs) obtained using HP-filter. Control variables, such as the growth rates of domestic credit to private sector and real investment, are included in both models.

A-D. Bars show the estimated coefficients for the lagged cyclical component of official GDP.

FIGURE 3C.3 Correlations of informal output with formal output: Shares of informal output and employment

Both shares of informal output and shares of informal employment are negatively correlated with formal-economy output, while shares of formal employment are positively correlated.

Note: Data are for 1990-2018. AEs = advanced economies; DGE = dynamic general equilibrium model estimates; EMDEs = emerging market and developing economies; MIMIC = multiple indicators and multiple causes model estimates. Formal employment is proxied by total employment excluding self-employment. Informal employment is proxied by self-employment. *** denotes 10 percent significance. A-B. Bars show the correlations between the cyclical components of formal-economy output (in logs) in year t(-2), t(-1) and t(0), respectively, and the cyclical components of informal output shares in year t(0). Both DGE-based and MIMIC-bases estimates on informal output are in percent of official GDP.

C-D. Bars show the correlations between the cyclical components of formal-economy output (in logs) in year t(-2), t(-1) and t(0), respectively, and the cyclical components of employment shares in year t(0). Formal employment (in C) is proxied by total employment excluding self-employment and expressed in percent of total employment. Informal employment (in D) is proxied by self-employment in percent of total employment.

FIGURE 3C.4 Impact of formal output fluctuations on shares of output and employment in the informal sector

During formal-economy recessions, formal-economy output shrinks slightly more than informal-economy output, raising the share of informal-economy output in percent of official GDP. Meanwhile, formal employment shrinks and informal employment remains stable, resulting in a rising share of informal employment.

A. Impact of formal output fluctuations on informal output: Full set

B. Impact of formal output fluctuations on employment: Full set

C. Impact of formal output fluctuations on informal output: Trade-related variables

D. Impact of formal output fluctuations on employment: Trade-related variables

Source: World Bank.

Note: Data are for 1990-2018. See annex 3C for details. AEs = advanced economies; DGE = dynamic general equilibrium model estimates; EMDEs = emerging market and developing economies; MIMIC = multiple indicators and multiple causes model estimates. Formal employment is proxied by total employment excluding self-employment. Informal employment is proxied by self-employment. "Full set" are models where both government consumption and trade-related variables (proxied by terms of trade and export) are included as instrumental variables (IVs) to explain the variation in formal output (proxied by official GDP). "Trade-related variables" are models where only trade-related variables are used as IVs. *** denotes 10 percent significance.

A.C. Bars show estimated coefficients when DGE (MIMIC)-based estimates (in percent of official GDP) are used as the dependent variable.

B.D. Bars show estimated coefficients when formal employment (informal employment proxied by self-employment; in percent of total employment) is used as the dependent variable.

ANNEX 3D Calibrating DGE estimates using survey-based self-employment data

As shown in Elgin and Oztunali (2012), the employment in the informal sector, N_{It} has the following form:

$$N_{It} = \left\{ \frac{\gamma A_{It}}{(1-\tau_t)(1-\alpha)A_{Ft}} \left[\frac{\frac{1}{\beta} - 1 + \delta}{\alpha(1-\tau_t)A_{Ft}} \right]^{\frac{\alpha}{1-\alpha}} \right\}^{\frac{1}{1-\gamma}} \quad \text{Eq(1).}$$

After transforming Eq (1), A_{It} can be expressed as follows:

$$A_{It} = \frac{N_{It}^{1-\gamma}(1-\tau_t)(1-\alpha)A_{Ft}}{\gamma \left[\frac{\frac{1}{\beta} - 1 + \delta}{\alpha(1-\tau_t)A_{Ft}} \right]^{\frac{\alpha}{1-\alpha}}} \quad \text{Eq(2).}$$

Following Fiess, Fugazza, and Maloney (2010) and Loayza and Rigolini (2011), data on self-employment, as shown in chapter 1, is used as estimates for N_{It} and calculate A_{It} using Eq (2). Following the earlier literature, α is assumed to be equal to 0.36 while δ takes the country average of the depreciation rates reported in Penn World Table 9.1 (PWT). Following Ihrig and Moe (2004), γ takes 0.425. Capital stock (K_t) and formal employment (N_{Ft}) are obtained from PWT 9.1. Assuming a balanced budget for the government, τ_t is obtained as the share of government spending in GDP reported in PWT 9.1.

Rewriting the production function of the informal sector (Y_{It}) using Eq(2), Y_{It} is a function of A_{Ft} and N_{It} :

$$Y_{It} = N_{It} * \frac{(1-\tau_t)(1-\alpha)}{\gamma \left[\frac{\frac{1}{\beta} - 1 + \delta}{\alpha(1-\tau_t)} \right]^{\frac{\alpha}{1-\alpha}}} * (A_{Ft})^{\frac{1}{1-\alpha}},$$

which gives $\frac{\partial Y_{It}}{\partial A_{Ft}} > 0$. Since $\frac{\partial Y_{Ft}}{\partial A_{Ft}} > 0$, it is possible that the DGE estimates will move procyclically in the presence of large shocks in formal productivity while other type of shocks is absent. However, when other type of shocks also occurs at the same time, Y_{It} may not move procyclically. For instance, if N_{It} and N_{Ft} experienced shocks in different directions in the same time, Y_{It} might move countercyclically in the absence of other types of shocks.

Note: Robust standard errors in parentheses; ** p<0.01, * p<0.05, + p<0.1. First-stage F-stat show whether the concerning variable is a weak instrumental variable (IV), with a higher value suggesting a stronger IV. The equation is exactly identified. Kleibergen-Paap rk LM statistic shows the results for under-identification test, where a rejection shows the instrument is relevant. Significant Cragg-Donald Wald F statistic also shows that the used instrument is strong. Formal employment is total employment (excl. self-employment). Informal employment is proxied by self-employment. All dependent variables: official GDP, export and government consumption are cyclical components (in logs) obtained using HP-filter. Terms of trade is cyclical component (in percent of trend) obtained using HP-filter. Official GDP, government consumption, terms of trade and export are lagged to deal with the endogeneity issue. The control variables include the growth rates of domestic credit to private sector and real investment. See annex 3C for details. Full sample with period over 1990-2018 is used here.

Professor of Economics, Harvard University

PART II

Country and Regional Dimensions

CHAPTER 4

Lagging Behind: Informality and Development

Informality is associated with a wide range of development challenges. Emerging market and developing economies (EMDEs) with greater informality have significantly lower per capita incomes and greater poverty, less developed financial markets, weaker governance and public service provision, poorer human development outcomes, and more limited access to public infrastructure. This wide range of correlates suggests that any policies to address informality need to be embedded in a broader development agenda.

Introduction

Informal activity is widespread in emerging market and developing economies (EMDEs). While informality is often considered a cause of development challenges, informality itself is also a consequence of under-development.¹ EMDEs with more pervasive informality tend to be less developed; rely more on labor-intensive activities that employ unskilled and poorly paid workers; and have limited fiscal resources (World Bank 2019). Life expectancy, maternal mortality and other human-development indicators are, on average, lagging behind in EMDEs with more pervasive informality. Access to public services, such as electricity provision, that are essential to economic development, is limited.

A large informal sector weakens policy effectiveness and the government's ability to generate fiscal revenues.² Government revenues in EMDEs with above-median informality are 5-12 percentage points of GDP below those with below-median informality (World Bank 2019). Limited fiscal resources constrain governments' ability to offer adequate coverage of social protection programs, provide broad access to public sector services, smooth business cycles, and close the productivity gap between the formal and informal sectors (Schneider, Buehn, and Montenegro 2010; World Bank 2020a). In turn, the limited access to public services further discourages firms and workers from engaging with the government, resulting in more participation in the informal sector (Loayza 2018; Perry et al. 2007).

EMDEs with widespread informality score particularly poorly on indicators of development. Many development outcomes are captured and quantified in measures of progress toward the Sustainable Development Goals (SDGs). There are 17 SDGs, each

Note: This chapter was prepared by Franziska Ohnsorge, Yoki Okawa, and Shu Yu. Research assistance was provided by Lorez Qehaja, Arika Kayastha and Jinxin Wu.

FIGURE 4.1 Development challenges and informality

EMDEs with more pervasive informality face severe development challenges, ranging from extreme poverty to lack of public infrastructure, and lag behind in progress toward the Sustainable Development Goals (SDGs).

A. SDG Global Index rank

B. Extreme poverty headcount

Sources: Sachs et al. (2020); World Bank (World Development Indicators).

Note: "High informality" ("Low informality") are EMDEs with an above-median (below-median) DGE-based informal output measure over the period 1990-2018. EMDEs = emerging market and developing economies; DGE = dynamic general equilibrium model-based estimates in percent of official GDP. Results are robust to regressions using quartile dummies (table 4.14). Based on 132 EMDEs (A) or 155 EMDEs (B). *** indicates that group differences are significant at the 10 percent level.

A. Bars show group averages for the latest year available (that is, 2020). SDG global index rank provides the economy's rank regarding SDG achievement, with a high value suggesting lack of SDG achievement.

B. Bars show group averages for EMDEs with "high informality" and "low informality" in 2000 and the latest year available. Poverty headcount ratio at \$1.90 a day is the percentage of the population living on less than \$1.90 a day at 2011 international prices.

with multiple underlying targets and associated data indicators, to be achieved by 2030. They add specificity to the broad objectives of ending poverty, protecting the planet, and ensuring shared prosperity (Vorisek and Yu 2020). They were adopted in 2015 as a key component of the 2030 Agenda for Sustainable Development. They include human-development-related goals, such as an end to poverty, zero hunger, reduced inequality, high-quality education and health-care services, and also infrastructure-related goals, such as access to clean water, sanitation, and affordable clean energy. Despite recent improvements, progress toward the SDGs has been uneven.

In 2020, EMDEs with above-median informality, on average, ranked around 110 out of 166 in overall SDG achievement, which is significantly worse than EMDEs with below-median informality (figure 4.1).³ In 2018, 26 percent of the population of EMDEs with above-median informality lived in extreme poverty, much more than the 7 percent of the population in EMDEs with below-median informality. In countries with greater informality, income inequality was higher, in part reflecting the wage gap between formal and informal workers and less progressive tax policies (box 4.1; Chong and Gradstein 2007; World Bank 2019).

³Unless otherwise specified, informality refers to dynamic general equilibrium (DGE)-based estimates of informal output in percent of official GDP. Results pertaining to employment informality, proxied by self-employment in percent of total employment, are shown in table 4.12 and table 4.15.

BOX 4.1 Informality and wage inequality

An extensive literature has documented the wage penalty for workers in the informal economy compared to their peers in the formal economy. Estimates of this penalty, however, vary substantially across countries. A comprehensive review of the relevant empirical studies suggests that the wage penalty largely reflects the characteristics of workers who self-select into informal activities.

Worldwide, two billion people, or more than 60 percent of all workers aged 15 and over, have informal jobs (ILO 2018a). Informality is often associated with lower wages than the formal sector. If these lower wages reflect a wage penalty for informality that is independent of worker characteristics, policies that encouraged the movement of workers to the formal sector might be a powerful remedy for income inequality and poverty. If, however, the wage differential largely reflects the characteristics of the workers employed in the informal sector, moving workers to the formal sector would be unlikely to achieve such gains.

Persistent informality frequently overlaps with poverty as many working poor remain employed in the informal sector (ILO 2018b; box 4.3). Lower wages in the informal sector can result from different worker characteristics, possibly reflecting comparative advantage, or reflect non-wage benefits that might accrue to work in the informal sector (Heckman and Li 2003; Maloney 2004). Wage differences may also reflect subjective well-being or job satisfaction of workers in the formal and informal sectors, with informal jobs offering more flexibility and independence (e.g., Blanchflower, Oswald, and Stutzer 2001; Falco et al. 2011; Sanfey and Teksoz 2007). Alternatively, wage differentials could stem from rigidities and other factors that create a wedge in wages between similar workers in informal and formal employment (Harris and Todaro 1970).

This box sifts through a large body of empirical evidence on informal wage differentials to explore the following questions:

- What factors can create wage differentials between formal and informal sectors?
- How large is the wage gap between formal and informal jobs?
- What accounts for the wage gap between formal and informal jobs?

A comprehensive review of empirical models, identification strategies, estimation methods, and data sources delivers mixed results. Some studies detect a substantial formal wage premium over informal employment; other estimates, however, do not find a significant wage gap after controlling for individual and firm-specific characteristics. In light of these different findings, a Meta-Regression

BOX 4.1 Informality and wage inequality (*continued*)

Analysis (MRA) is used to aggregate multi-study estimates of the formal wage premium and obtain a quantitative assessment of the sources of cross-study variation in research outcomes.

Causes of wage differentials

Wage differentials between formal and informal employment reflect a confluence of worker-, job- and country-specific characteristics. Broadly speaking, differentials can reflect inefficiencies caused by labor market frictions or self-selection of workers into their most productive employment—with diametrically opposed policy implications.

Segmented labor markets. Lower informal wages may result from workers being rationed out of better-paying formal jobs. For example, García and Badillo (2018) find that formal job rationing may affect over 60 percent of the workers in the informal sector of Colombia. Rigidities in the formal job market induced by, for example, labor regulations, unions, tax laws and labor regulations or efficiency wages may restrict competitive access to formal jobs. This creates a wedge in wages between formal and informal employment for workers of equal productivity (Harris and Todaro 1970). Formal wage premiums may also reflect better job matches in formal activities, particularly in denser and larger urban areas (Matano, Obaco, and Royuela 2020).

Self-selection into informal employment. A wage differential can also arise because of worker preferences. Workers may self-select into informal employment, either because of desirable non-wage benefits or amenities attached to informal jobs or because they have a comparative advantage—that is typically unobserved in research studies—in informal sector activities (Heckman and Li 2003; Maloney 2004). A worker may stay at a lower-paying informal job simply because the opportunity cost of foregone wages in the formal sector does not offset non-monetary benefits of informal employment, such as greater autonomy and more flexible working hours relative to a formal, salaried job.

Characteristics of informal workers. In EMDEs, self-employed workers constitute the core of informal employment; they typically lack registration at the national level, do not contribute to social security, and are not entitled to paid annual or sick leave.^a However, not all informal workers are self-employed, and the informal sector itself may be divided into tiers such as informal self-employed entrepreneurs or professional workers and informal non-professional employees.^b In EMDEs, about half of informal workers are non-professional self-employed

a. According to ILO (2018b), nearly 90 percent of all own-account workers—the largest component of self-employed in EMDEs—are in the informal sector, accounting for over 45 percent of all informal jobs.

b. See Cunningham and Maloney (2001); Fields (1990, 2005); and Günther and Launov (2006).

BOX 4.1 Informality and wage inequality (*continued*)

workers—who migrate to formal employment as per capita incomes grow—and the majority of the remainder are informal employees (Gindling, Mossaad and Newhouse 2016). Depending on the restrictiveness of regulations and the quality of education systems, the composition of informal employment varies across countries and EMDE regions. For example, contributing family members (predominantly women) and the self-employed are the majority of informal workers in developing Asia and Africa, where public education systems can be rudimentary, whereas informal employees and employers dominate the informal sector in Europe and Central Asia and in Latin America where tax and business regulations can be burdensome (ILO 2018b).

Interpreting the literature

Selection of studies. The representative sample of studies on informality and wage inequality used here follows the selection guidelines in Stanley et al. (2013) and is broadly similar to criteria applied by van der Sluis, van Praag, and Vijverberg (2005). An initial search was conducted in the major English language repositories of academic articles and working papers.^c A study was included in the database if it: (i) provided a quantitative estimate of the informal-formal wage gap and a corresponding standard error or t-statistic; (ii) used data from micro-level household or labor surveys to obtain these estimates; (iii) analyzed an EMDE or group of EMDEs as defined by the World Bank classification and (iv) was published no earlier than 1990.^d The resulting database included 18 studies with a total of 83 individual coefficient estimates covering 20 EMDEs (annex 4A, table 4.1).

Definitions matter. Differences in estimates of the incidence of informal employment and the wage differentials between formal and informal workers in part reflect differences in data coverage and definitions of informal workers.^e Studies typically find that self-employed informal workers earn the same or more than formal workers, but employed informal workers earn less than formal workers (figure B4.1.1; Abraham 2019).^f In EMDEs with more restrictive business regulations, however, self-employment may be associated with a higher wage penalty because less favorable business climates may deter more productive

c. Covered online databases include EBSCO, EconLit, Google Scholar, JSTOR, International Monetary Fund Working Paper series, IZA Working Papers, the National Bureau of Economic Research (NBER), RePEc, Social Science Research Network (SSRN), and World Bank Policy Research Working Paper series.

d. Prior to 1990, reliable and comparable individual or household level survey data, which is used to estimate wage gaps between the formal and informal sectors, are very limited for developing countries.

e. See Hussmanns (2004); ILO (2013); and Perry et al. (2007).

f. See Arias and Khamis (2008); Kahyalar et al. (2018); Lehmann and Pignatti (2007); Maloney (1999); and Nguyen, Nordman, and Roubaud (2013).

BOX 4.1 Informality and wage inequality (continued)

workers, particularly women, from transitioning to non-professional self-employment (Gindling, Mossaad, and Newhouse 2020).

Methodology matters. Empirical research on the wage differential between informal and formal workers has largely relied on estimating “Mincerian” wage regressions conditional on the observed characteristics of workers, although more recent studies have used quantile regressions to assess sector wage gaps along the wage distribution.^g Such cross-sectional wage regressions are biased when workers’ unobserved characteristics affect both their occupational choice and wages. For example, several studies find workers transitioning from the formal sector into the informal sector after spending several years accumulating experience and knowledge in the formal sector (Gong, van Soest, and Villagomez 2004; Maloney 2004). Hence, studies that rely on panel data to control for time-invariant unobserved worker characteristics find smaller informal-formal wage differentials (Botelho and Ponczek 2011; Cho and Cho 2011; El Badaoui, Strobl, and Walsh 2008; Tansel, Keskin, and Ozdemir 2020). Similarly, semiparametric matching models, such as propensity score matching and difference-in-difference estimators that are immune to the misspecification of the wage regressions, find modest or insignificant wage differentials between formal and informal jobs (Pratap and Quintin 2006).

Empirical estimates of wage differentials

Wage differentials. The estimates of the wage differential between informal and formal workers in the 18 studies selected here range from a formal sector wage penalty of 50 percent in Tajikistan (Huber and Rahimov 2014) to a formal sector wage premium of 113 percent in South Africa (El Badaoui, Strobl, and Walsh 2008) with a median formal wage premium of about 18 percent.^h On average, the random-effects meta-analysis estimate of the wage premium in the formal sector obtained from pooling all studies is 19 percent (figure B4.1.1 and table 4.2).ⁱ

Explaining wage differentials. The wage premium largely disappears in studies using worker fixed effects, which are controlling for unobserved characteristics of

g. See Bargain and Kwenda (2014); Lehmann and Zaiceva (2013); and Tansel and Kan (2012).

h. A formal-sector wage premium indicates that formal-sector wages exceed those in the informal sector, whereas a formal sector wage penalty indicates formal-sector wages are below informal-sector wages. Huber and Rahimov (2014) attribute a large formal wage penalty in Tajikistan to self-selection and find no evidence of labor market segmentation. Meanwhile, El Badaoui, Strobl, and Walsh (2008) find that a formal wage premium in South Africa disappears once they controlled for unobserved worker characteristics.

i. See annex 4A for technical details.

BOX 4.1 Informality and wage inequality (continued)

FIGURE B4.1.1 EMDEs: Estimates of informal-formal wage gaps

Estimates of informal-formal wage gaps vary considerably across countries and definitions of informality. Countries in Latin America and the Caribbean and Sub-Saharan Africa tend to exhibit both a higher incidence of informality and a larger wage premium in the formal sector.

A. EMDEs: Informal-formal wage gaps

B. Informal-formal wage gaps: meta-analysis

C. Informal-formal wage gaps

D. Informal-formal wage gap and income inequality by EMDE regions

Sources: Gindling, Mossaad, and Newhouse (2016); World Bank.

Note: A positive wage gap indicates a penalty for working informally—a lower wage for informal workers than for comparable formal workers. A negative wage gap indicates a premium for working informally—a higher wage for informal workers than for comparable formal workers. EAP = East Asia and Pacific; ECA = Europe and Central Asia; LAC = Latin America and the Caribbean; MNA = Middle East and North Africa; SAR = South Asia; SSA = Sub-Saharan Africa. Wage gap between wage employees in the informal and formal sectors is displayed on the vertical axis.

A. Formal vs. informal = a wage gap between wage employees in the formal and informal sectors; Formal vs. self-employed = a wage gap between workers with formal jobs and self-employed workers; Self-employed vs. informal = a wage gap between self-employed workers and wage employees in the informal sector.

B. BRA = Brazil; CRI = Costa Rica; ECU = Ecuador; MDG = Madagascar; MEX = Mexico; PER = Peru; RUS = Russian Federation; SLV = El Salvador; TUR = Turkey; UKR = Ukraine; VNM = Vietnam; ZAF = South Africa. The number of studies or estimates for each economy is shown in parenthesis; economy means are calculated using a random-effects meta-analysis model.

C. The wage premium (shown in bars) is obtained from 18 empirical studies of the wage gap between formal and informal workers. The whiskers show the 90 percent confidence intervals. See box 4.1 for details.

D. Income inequality is measured as Gini coefficient provided by the World Bank's World Development Indicators.

BOX 4.1 Informality and wage inequality (continued)

workers.^j It turns into a statistically insignificant 8 percent penalty in studies that compared wages of self-employed informal workers with formal-sector employees.^k Informal employment tends to be associated with low levels of education and a U-shaped age profile and is more prevalent in rural areas, where there are fewer job alternatives in the formal sector (Gasparini and Tornarolli 2007; Hazans 2011).^l In general, low productivity attributes of workers in the informal sector may limit their earnings potential in comparable formal jobs.

Country characteristics. Even after controlling for study and sample-specific attributes, most of the cross-study variation in the estimates of the wage differential remains unexplained. That said, wage premia tend to be higher where informality is more widespread (figure B4.1.1). Differentials are particularly wide in Latin America and the Caribbean and Sub-Saharan Africa but below-average in Europe and Central Asia and South Asia (figure B4.1.1). Overall, the data do not offer strong evidence of a significant relationship between the size of the formal sector wage premium and the level of development or the quality of institutions.

Conclusion

Despite years of declining poverty, many working poor remain employed in the informal sector where they face significantly lower wages than workers in the formal economy. Estimates of the formal sector wage premium vary widely but, in the meta-analysis of the 18 studies conducted here, amount to just under 20 percent of informal wages. However, among studies controlling for worker characteristics, there is no statistically significant evidence of a formal sector wage premium.

This suggests that any formal-informal wage differential is largely a reflection of the characteristics of the types of workers who self-select into informal and formal employment. Workers in the informal sector tend to be less-skilled, younger or older, and more agricultural than workers in the formal sector. This points to the need for policies to lift these workers' human capital and, thus, allow them to switch into productive formal employment.

j. In the regression in annex 4A, the informal-formal wage gap for studies using fixed worker effects is estimated as the sum of the coefficients for μ and *FE*, tested for joint significance: the test statistic $F(1,76) = 0.41$ indicates that the null hypothesis of a zero sum of two coefficients cannot be rejected at any conventional significance level.

k. In the regression in annex 4A, the wage premium for self-employed is estimated as the sum of the coefficients for μ and *Self-employed*, tested for joint significance: the test statistic $F(1,76) = 0.33$ indicates that the null hypothesis of a zero sum of two coefficients cannot be rejected at any conventional significance level.

l. Younger and older workers are typically less productive, while older retired workers may be choosing informal employment to supplement their social security benefits.

It would take substantial additional financial resources to meet the SDGs by 2030, even if they were accompanied by big strides in policy improvements (UN SDSN 2019; Vorisek and Yu 2020). The World Bank estimates that low- and middle-income countries face additional investment needs of \$1.5-2.7 trillion per year between 2015 and 2030 to meet infrastructure-related SDGs alone (Rozenberg and Fay 2019). The IMF estimates that additional spending of about \$1.3 trillion per year during 2019–30 is required to make meaningful progress toward infrastructure-related SDGs in EMDEs, and another \$1.3 trillion for human-development-related SDGs (Gaspar et al. 2019). The UN estimates that an additional \$400 billion per year is needed in lower-income developing countries between 2019 and 2030, mainly for social protection, health, education, and climate change mitigation and adaptation (UN SDSN 2019).

Against this backdrop, this chapter addresses the following questions:

- What are the development challenges associated with the informal economy?
- What are the correlates of widespread informality?
- What are the correlates of changes in the informal sector over time?

Contributions. The chapter makes the following contributions to the literature on informality. First, it provides a systematic and comprehensive overview of developmental challenges facing countries with large informal sectors, highlighting their association with a wide range of development weaknesses and shortfalls from the SDGs.⁴ Previous studies have focused on the economic or institutional correlates of informality—such as per capita income (for instance, La Porta and Shleifer 2014; Loayza, Servén, and Sugawara 2010) or control of corruption (for instance, Choi and Thum 2005; Dreher and Schneider 2010)—and largely disregarded the linkages between informality and other aspects of sustainable development, ranging from life expectancy to lack of access to public infrastructure.

Second, the chapter is the first published study to empirically and systematically examine a broad range of correlates of informality in a large group of EMDEs, numbering around 130. Previous studies have tended to focus on one dimension of informality, rely on a more limited range of correlates, and only examine the correlates of cross-country differences in informality without focusing on EMDEs. To identify the robust correlates of informality, the chapter is also the first to use a Bayesian Model Averaging (BMA) approach, which is designed to take account of model uncertainty (Fernandez, Ley, and Steel 2001).

Third, in three boxes, this chapter illustrates how informality can pose developmental challenges to EMDEs. Box 4.1 conducts the first extensive meta-analysis of studies that

⁴ See Medina and Schneider (2019); Oviedo, Thomas, and Karakurum-Özdemir (2009); and Schneider, Buehn, and Montenegro (2010).

documented wage differences for workers in formal and informal sectors. Box 4.2 utilizes a unique firm-level dataset to show how the productivity gap between formal and informal firms in EMDEs can be narrowed by improvements in business climates.⁵ Box 4.3 empirically tests whether there is a strong relationship between declines in informality and poverty reduction (or income inequality).

Main Findings. The chapter demonstrates that EMDEs with pervasive informality face a wider range of greater development challenges than other EMDEs. First, informality is associated with poor economic outcomes. Countries with larger informal sectors have lower per capita incomes, greater poverty, less financial development, and weaker growth in output, investment and productivity. Informal firms are less productive than their formal counterparts (box 4.2).

Second, more pervasive informality is associated with significantly lower government revenues and expenditures, less effective policy institutions, more burdensome tax and regulatory regimes, and weaker governance. Weaknesses in governance and revenue collection constrain the provision of public services in EMDEs with more pervasive informality, contributing to poorer human development outcomes. People living in EMDEs with more widespread informality suffer from a greater prevalence of hunger, poorer health and education, and greater gender inequality. Countries with more widespread informality offer poorer access to, and lower-quality, infrastructure.

Third, the results from the BMA approach suggest that economic development, human capital, and governance are particularly robust correlates of informality. That said, other correlates such as infrastructure, for instance, are also relevant.

Fourth, while informality is linked to a host of developmental challenges, formalization alone is unlikely to offer an effective path out of under-development. For instance, while declines in informality were associated with poverty reduction, they were not systematically linked to declining income inequality (box 4.3). This may reflect the fact that informality itself is a symptom of underdevelopment, in line with the meta-analysis of the literature that finds that the wage penalty largely reflects the characteristics of informal workers (box 4.1).

The following section summarizes the transmission mechanisms underlying the linkage between informality and development challenges. Here informality is regarded as both a cause and a consequence of underdevelopment: there are reasons to expect causation potentially to run in both directions. The subsequent sections examine the economic and institutional correlates of informality, followed by sections that describe the link between informality and various SDGs. The penultimate section summarizes the finding of the Bayesian Model Averaging approach, followed by a conclusion in the final section.

⁵ Existing studies, such as Meghir, Narita, and Robin (2015) and Ulyssea (2018), explore the productivity gap between formal and informal firms in individual countries.

Links between informality and development challenges

EMDEs with widespread informality face relatively large development challenges. Informality may be linked with these challenges through several channels. For the purposes of the discussion here, informality refers to output informality, but the results are robust to using employment informality.

Low productivity, low incomes. Informal workers tend to be less skilled and lower paid than their formal counterparts (Loayza 2018; Perry et al. 2007; World Bank 2019). A meta-analysis of worker-level empirical studies shows that informal workers are, on average, paid 19 percent less than formal workers (figure 4.2; World Bank 2019). In part, this reflects lower productivity on account of lower skill and experience levels than formal workers have. The meta-analysis suggests that, when controlling for worker characteristics, the wage gap is no longer statistically significant (box 4.1).⁶ In 2020, these features made participants in the informal sector particularly vulnerable during lockdowns associated with the COVID-19 pandemic (World Bank 2020a; box 2.1).

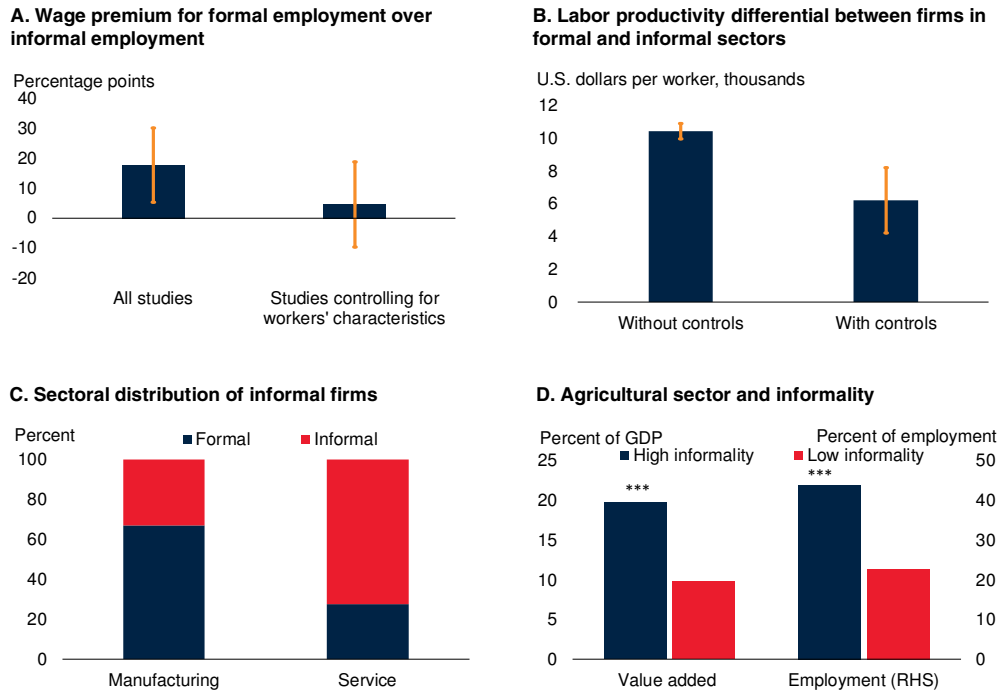

Similarly, informal firms tend to be small, lack funds, and operate in labor-intensive sectors, and, as a result, are less productive than formal firms (figure 4.2; Fajnzylber, Maloney, and Montes-Rojas 2011; Farazi 2014; McKenzie and Sakho 2010). They tend to invest less, possibly in an effort to avoid adopting technologies that would make them more visible to tax and other authorities (Dabla-Norris, Gradstein, and Inchauste 2008; Gandelman and Rasteletti 2017). For example, in about 11,600 firms that participated in Enterprise Surveys in 18 economies during 2007-2014, the fraction of formal firms that invested was significantly higher than that of informal firms. Low productivity in the informal sector can also cast a shadow over formal firms: a sizeable informal sector that competes with the formal sector for low-skilled workers reduces the incentives to invest in human and physical capital and new technologies and slows growth in the long run (box 4.2; Amin, Ohnsorge, and Okou 2019; Distinguin, Rugemintwari, and Tacneng 2016; Docquier, Müller and Naval 2017; Loayza 1996; Perry et al. 2007; Sarte 2000).

Sectoral distribution. Informal workers in EMDEs tend to be concentrated in the agricultural and services sectors (figure 4.2). Agricultural employment in EMDEs is about 90 percent informal. In EMDEs with above-median informality, the agricultural sector, on average, accounts for about 20 percent of GDP and for nearly 40 percent of total employment—almost twice as much as in EMDEs with below-median informality. In addition, informal firms tend to be smaller, less productive and concentrated in labor-intensive sectors, such as low-value-added services. In EMDE service sectors, about 72 percent of firms are informal, compared with 33 percent in manufacturing (World Bank

⁶This lower productivity may also account for the inability of the formal sector in cities to absorb rural migrants during the urbanization process (Fields 1975; Harris and Todaro 1970; Loayza 2016).

FIGURE 4.2 Features of informal firms and workers

Informal workers tend to be less well-paid and employed in the agricultural or services sectors. Informal firms are less productive than their formal-sector peers.

Sources: Amin, Ohnsorge, and Okou (2019); World Bank (Enterprise Surveys, World Development Indicators); World Bank.

A. The wage premium (shown in bars) is obtained from 18 empirical studies of the wage gap between formal and informal workers. The whiskers show the 90 percent confidence intervals. See box 4.1 for details.

B. Difference between labor productivity of formal and informal firms, without controlling for firm characteristics and with controlling for firm characteristics. Firm productivity is measured as sales per worker in 2009 U.S. dollars. Whiskers show the corresponding ± 2 standard errors.

C. See Amin, Ohnsorge, and Okou (2019) for data coverage.

D. Bars are group means from the latest year available calculated for EMDEs with "high informality" (that is, above-median DGE-based informal output in percent of GDP) and those with "low informality" (EMDEs with below-median DGE-based informal output measure) over the period 1990-2018. DGE stands for dynamic general equilibrium model-based estimates. EMDEs = emerging market and developing economies. *** indicates group differences are not zero at 10 percent significance level.

2020a).⁷ Large productivity gaps exist between manufacturing, agricultural, and service sectors in EMDEs (Dieppe 2020).

Access to resources. In EMDEs with widespread informality, access to finance and public resources is limited. Informal firms struggle to access conventional banks because of lack of property rights, lack of documentation for assets, and inadequate financial statements (Bose, Capasso, and Wurm 2012; de Soto 1989). In the World Bank's

⁷As these economies grow richer, households tend to shift away from agricultural and informal sector goods (Saracoğlu 2008).

FIGURE 4.3 Access to finance and public services

In EMDEs with more pervasive informality, access to external finance and public services is more limited, constraining productivity and entrepreneurship.

A. Firms' financing conditions and informality**B. Financial development and informality****C. Household access to finance and informality****D. Entrepreneurial framework conditions and informality**

Sources: International Monetary Fund (Financial Development Database); World Bank (Enterprise Surveys, Global Financial Development Database, World Development Indicators).

Note: "High informality" ("Low informality") are emerging market and developing economies (EMDEs) with above-median (below-median) dynamic general equilibrium (DGE)-based informal output measures. *** indicates group differences are not zero at 10 percent significance level.

A. Bars are group means for EMDEs over the period 2000-18. "Finance constraint" measures the percent of firms identifying access to finance as a major constraint. "Bank finance" measures the percent of firms using banks to finance investment. "Internal finance" measures the average proportion of investment financed internally.

B. Bars show simple averages for EMDEs over the period 2010-18. "Financial development (overall)" is the aggregate financial development index from the IMF's Global Financial Development Database. It purports to measure the overall level of financial development, in both "financial institutions" and "financial markets." The latter refers to the accessibility, depth, and efficiency of an economy's stock and debt markets, which is less relevant for informal participants in EMDEs. The "Institutions" index measures how developed financial institutions are in terms of their depth (size and liquidity), accessibility (ability of individuals and companies to access financial services), and efficiency (ability of institutions to provide financial services at low cost and with sustainable revenues).

C. Bars are unweighted group averages for EMDEs over the period 2010-18. "Bank branches" measures the number of commercial bank branches per 100,000 adults. "ATMs" measures the number of automated teller machines (ATMs) per 100,000 adults. "Private credit" measures domestic credit to private sector in percent of GDP. "Account ownership" is the percentage of survey respondents (aged 15 and above) who report having an account (by themselves or together with someone else) at a bank or other financial institution, or report personally using a mobile money service in the past 12 months. "Internal financing" refers to the percentage of respondents (aged 15 and above) who report saving or setting aside any money in the past 12 months to start, operate, or expand a farm or business.

D. Bars are group means for EMDEs over the period 2000-18. The score is based on the Global Entrepreneurship Monitor's National Expert Survey. Ranging from 1 to 9, a higher score represents better perceived conditions. Basic training = extent to which training in creating or managing small and medium-sized enterprises (SMEs) is incorporated within the education and training system at primary and secondary levels; Business infrastructure = presence of property rights that support or promote SMEs, including commercial, accounting, and other legal and assessment services and institutions; Physical infrastructure = ease of access to physical resources, communications, utilities, transportation, land, or space at a price that does not discriminate against SMEs. Outliers (Saudi Arabia and Kuwait), are not included.

BOX 4.2 Casting a shadow: Productivity in formal and informal firms

Labor productivity in the average informal firm in emerging market and developing economies (EMDEs) is only one-quarter of that of the average firm operating in the formal sector. Moreover, firms in the formal sector that face informal competition are, on average, only three-quarters as productive as those that do not. This suggests that competition from the informal sector can erode formal firms' market share and resources available to boost productivity as they shoulder the costs of regulatory compliance. More effective governance and stronger control of corruption can help mitigate these effects.

Introduction

The differential in labor productivity between formal and informal firms is well established in the literature (Loayza and Rigolini 2006; Oviedo 2009). However, there is mixed evidence on the impact of a large informal sector on formal firms' labor productivity.^a Some studies suggest that the informal and formal sectors operate independently so that there are no productivity spillovers (La Porta and Shleifer 2014). Others report that competition from the informal sector may erode the profitability of firms in the formal sector, limiting their resources to enhance firm productivity. The aggregate effect varies with country characteristics (Amin and Okou 2020).

Against this backdrop, this box documents the productivity gap between formal and informal firms and their interactions. Specifically, it addresses the following questions:

- How large is the differential in labor productivity between formal and informal firms?
- To what extent are formal firms exposed to informal competition?
- How does informal competition affect the labor productivity of formal firms?

Productivity differential between formal and informal firms

Literature review. The literature documents that informal firms in EMDEs are less productive than formal firms, with labor productivity gaps ranging between 30 and 216 percent (La Porta and Shleifer 2008; Perry et al. 2007). The productivity gap between informal and formal firms is attributed to more backward technologies in informal firms, their greater reliance on unskilled labor,

Note: This box was prepared by Mohammad Amin and Cedric Okou. The box closely follows box 3.3 in the January 2019 *Global Economic Prospects* report.

a. See Gonzalez and Lamanna (2007); Heredia et al. (2017); and Mendi and Costamagna (2017).

BOX 4.2 Casting a shadow: Productivity in formal and informal firms (continued)

their more limited economies of scale, and their more restricted access to services, markets, and funding.^b Labor productivity has also been found to vary within the informal sector along different dimensions such as firm size and type of activity (Amin and Huang 2014; Amin and Islam 2015).

Methodology. In this box, the labor productivity gap between formal and informal firms is estimated using the World Bank’s Enterprise Surveys data collected over the period 2007-14 for a cross-section of 4,036 informal firms and 7,558 formal firms in 18 EMDEs. Formal firms are those that register with the relevant authorities; unregistered firms belong to the informal sector. To estimate the productivity gap, a measure of labor productivity—log annual sales in 2009 U.S. dollars per worker—is regressed on a dummy variable that takes the value 1 for informal firms and 0 otherwise and a set of control variables capturing additional firm characteristics (employment size, time in business, location, sector, economy).^c

Lower productivity in informal than formal firms. Virtually across the board, firm-level labor productivity is much lower in the informal sector than in the formal sector (table 4.3).^d The productivity differentials vary widely in this sample, from 48 (Côte-d’Ivoire) to 93 percent (Argentina). On average across the whole sample, labor productivity in informal firms is only one-quarter of labor productivity in formal firms.

Drivers of productivity gap between informal and formal firms. Firm size, age, location in the capital city and manager experience are associated with significantly larger productivity gaps between informal and formal sectors (figure B4.2.1; table 4.4). Formal firms appear to be better equipped to reap productivity benefits from large size, advanced age, and urban location than informal firms.

- *Firm age.* As firms grow older, they are either sufficiently productive to survive or they disappear (“selection effect”; Brandt, Van Biesebroeck, and Zhang 2012). In addition, learning from experience may have taught older firms lessons that deliver productivity gains (“learning effect”; Luttmer 2007). These effects appear to be much more pronounced among formal firms than among informal firms. As a result, the productivity differential

b. See Amaral and Quintin (2006); Galiani and Weinschelbaum (2012); and Jovanovic (1982).

c. Commonly used revenue-based measures of productivity may conflate efficiency and price effects. Disentangling these effects, by using physical productivity measures, may shed new light on productivity patterns, especially at the firm level (Cusolito and Maloney 2018; Jones and Nordhaus 2008).

d. Exceptions are the Democratic Republic of Congo and Cabo Verde, possibly due to low productivity of formal firms.

BOX 4.2 Casting a shadow: Productivity in formal and informal firms (continued)

FIGURE B4.2.1 Labor productivity in informal firms

In EMDEs, labor productivity is significantly higher in informal firms that have managers with higher education and in those without any employees other than the owner. This labor productivity differential between formal and informal firms is particularly pronounced among larger and older firms that operate in the capital city and are led by experienced managers.

A. Cross-country average of percent difference between labor productivity in the median informal firm with a manager with higher education or without any employees other than the owner, and the median informal firm with a manager without higher education or with more employees than the owner. Estimates from table 4.3.

B. Difference between productivity of formal and informal firms, with and without controlling for other firm characteristics. Labor productivity in the average formal and average informal firm, controlling for firm characteristics (firm size and age, manufacturing sector activity, location in the capital city, and country fixed effects) as shown in column (1) in table 4.4.

C.D. Difference in log of labor productivity between the average formal and average informal firm in each group, as estimated in coefficient estimates of table 4.4. "Not in capital" stands for "not located in capital city"; "In capital" stands for "located in capital city."

BOX 4.2 Casting a shadow: Productivity in formal and informal firms (continued)

between formal and informal firms widens as the age of firms increases. Among one-year-old firms, informal firms have about half the labor productivity of formal firms. Among ten-year-old firms, informal firms have less than one-quarter the labor productivity of formal firms.

- *Firm size.* Larger firms can reap economies of scale that raise their labor productivity compared to smaller firms. Again, in this sample, this effect appears to be stronger among formal firms than among informal firms. Among firms with one employee, informal firms have just under one-third the labor productivity of formal firms; among firms with ten employees, informal firms have less than one-quarter the productivity of formal firms.
- *Firm location.* Capital cities are typically among countries' largest economic centers and so can offer agglomeration benefits, such as larger markets, better infrastructure to access markets and operate, a larger pool of workers, and greater technology spillovers (Duranton and Puga 2004; Rosenthal and Strange 2004). Again, formal firms appear to be better able to benefit from these locational advantages, though the difference is economically modest (although statistically significant). Among firms operating inside the capital city, informal firms' productivity is 31 percent that of similar formal firms; outside the capital city, informal firms' productivity is 30 percent that of similar formal firms.
- *Manager experience.* Managerial ability has been associated with higher labor productivity, through a variety of channels including hiring decisions and input choices (Fernandes 2008). Again, managerial experience appears to benefit formal firms' productivity more than informal firms' productivity. Among firms managed by managers with one year of experience, informal firms' labor productivity is just over one-third that of formal firms; among firms with managers with ten years of experience, informal firms' labor productivity is less than one-quarter that of formal firms.

Productivity differentials across informal firms. Labor productivity also differs across different types of informal firms, although the characteristics that are associated with higher labor productivity in informal firms differ across countries.^e In two-fifths of economies, informal firms having a manager with higher education or without any employees other than the owner are significantly more productive than other informal firms (column 1 in table 4.4). Other informal firm characteristics, such as operating in the services sector or being a

e. See Amin and Huang (2014); Amin and Islam (2015); de Mel, McKenzie, and Woodruff (2011); Deininger, Jin, and Sur (2007); Grimm et al. (2012); Haltiwanger, Lane, and Spletzer (1999); Islam (2018); and Maloney (2004).

BOX 4.2 Casting a shadow: Productivity in formal and informal firms (continued)

start-up, are accompanied by higher productivity in some countries but lower productivity in others.

Robustness tests. Labor productivity differentials between formal and informal firms remain significant when each control variable is included separately. They are also robust to including interaction terms of informality with firm characteristics that make “hiding” revenue more difficult, such as firm size, exporter status, location in the capital city or having reported fixed asset purchases (Amin and Okou 2020).

Productivity of formal firms amid high informality

Impact of informal competition on formal firms. The extent of competition between formal and informal firms depends partly on the reasons for the existence of the informal firms (Amin and Okou 2020).^f

- *Informality as a survival strategy of unproductive firms.* Low-productivity firms may be forced into informal operations or, if they continue to operate formally, into employing informal workers because this may reduce their costs (Boly 2018; Ulyssea 2018). Operating in the informal sector or employing informal labor may, therefore, be a survival strategy for less-productive firms. “Surviving” informal firms are likely to operate in very different markets and sell different products than formal firms (La Porta and Shleifer 2014). Competition between informal and formal firms and its impact on formal firms may then be limited.
- *Informality as an evasion strategy of productive firms.* Some informal firms may be sufficiently productive to survive in the formal sector yet choose to remain informal to benefit from the cost advantages of noncompliance with (possibly excessive) taxes and regulations (de Mel, McKenzie, and Woodruff 2011; Maloney 2004).^g Such informal firms could have untapped potential for a productivity boost (de Soto 1989). On the other hand, they can create aggressive competition with formal firms that do shoulder the additional cost of tax and regulatory compliance. Credit constraints tend to be higher for formal firms in sectors that host many informal firms (Distinguin,

f. This discussion assumes that firms are either formal or informal. In practice, the degree of informality can vary (Perry et al. 2007; Ulyssea 2018). Firms can operate fully informally, both in product markets and labor markets (“extensive margin”). They sell their output informally and employ informal labor. Or firms can operate semi-formally (“intensive margin”): they sell their output into formal product markets but employ, in part, informal labor, as observed in EMDEs and low-income countries.

g. Such circumstances are likely to be associated with an environment of weak regulatory and tax enforcement (Benjamin and Mbaye 2012; Dabla-Norris, Gradstein, and Inchauste 2008; Quintin 2008; Ulyssea 2010).

BOX 4.2 Casting a shadow: Productivity in formal and informal firms (continued)

Rugemintwari, and Tacneng 2016). Such informal competition can reduce the profitability necessary for formal firms to invest in productivity-enhancing new technologies or to innovate, especially in a context of weak property rights enforcement.^h Alternatively, this very competition could force formal firms to increase productivity or, for the lowest-productivity ones, to exit.ⁱ

Extent of informal-firm competition for formal firms. In the World Bank's nationally representative survey data for 75,137 formal (registered) firms in 135 economies between 2008 and 2018, about 55 percent of formal firms reported facing competition from informal firms.^j The share of informal firms competing against formal firms was about 60 percent in EMDEs, 13 percentage points higher than in advanced economies. The level of competition varied widely across economies, ranging from about 7 percent in Bhutan to 95 percent in Uganda. Smaller firms were significantly more likely to be exposed to informal competition than larger firms but there is little evidence of any other systematic difference between firms that were exposed and those that were not (figure B4.2.2).

Impact of informal competition on the productivity of formal firms

Methodology. Ordinary least squares regressions are used to estimate the difference in labor productivity between formal firms that compete against informal firms and those that do not. In the baseline specification, the dependent variable is again labor productivity measured by the (log of) annual sales per worker in 2009 U.S. dollars. The main explanatory variable is the informal competition indicator proxied by the proportion of other formal firms in a subgroup that report facing competition from informal firms. Such a subgroup is defined as a group of firms of similar size and in the same region and sector.^k

h. This has been documented for Latin America countries, India, Panama, Poland, Portugal, Russian Federation, and Turkey. For evidence, see Allen and Schipper (2016); Capp, Elstrodt, and Jones (2005); Distinguin, Rugemintwari, and Tacneng (2016); Farrell (2004); Friesen and Wacker (2013); Gonzalez and Lamanna (2007); Heredia et al. (2017); Iriyama, Kishore, Talukda (2016); Perry et al. (2007); and Vargas (2015).

i. This was documented for the Arab Republic of Egypt. See Ali and Najman (2017); Melitz (2003); and Schipper (2020).

j. In the World Bank's Enterprise Surveys, formal firms are asked the following question: "Does this establishment compete against unregistered or informal firms?"

k. As a caveat, the informal competition faced by a specific firm may also be driven by its low productivity, thus generating endogeneity concerns. To address this possible endogeneity issue, the proportion of formal firms facing informal competition in a group of firms of similar size in the same region and sector (a "cell") is used rather than a firm dummy. A cell proportion should be much less correlated with the productivity of a specific firm, and therefore, should be more robust to endogeneity concerns.

BOX 4.2 Casting a shadow: Productivity in formal and informal firms (continued)

FIGURE B4.2.2 Formal firms facing informal competition

A larger share of formal firms in EMDEs—about three-fifths—reported facing informal competition in 2008-18 than in advanced economies—about half. The degree of informal competition reported by formal firms was higher for smaller than for larger firms.

A. Formal firms reporting competition from informal firms: By country group

B. Formal firms reporting competition from informal firms: By firm size

Source: World Bank (Enterprise Surveys).

Note: World Bank's Enterprise Surveys data for 135 economies (2008-18). Figures show the shares of formal firms.

Productivity gap between formal firms with and without informal competition.

Formal firms that face informal competition are, on average, 24 percent less productive than those that do not (figure B4.2.3; table 4.5). After controlling for informal competition, formal firms in the manufacturing and retail industries have higher productivity than those in other services. Older, exporting, and foreign-owned formal firms also have higher productivity even if they face competition from informal firms.

Role of the business climate and development. Economic development and the business climate may substantially shape the productivity gap between formal firms that face informal competition and those that do not. This is captured in interaction terms between the share of similar formal firms reporting informal competition and indicators of development (the logarithm of per capita GDP), the quality of the business climate (proxied by the distance to the frontier in the World Bank Doing Business Dataset), the control of corruption as measured by the World Governance Indicators, and the Business Freedom Index of the Economic Freedom indicators (table 4.5). Higher GDP per capita, better control of corruption, and a business environment that is freer and closer to best practices were all found to dampen the detrimental impact of informal competition on formal firm productivity (figure B4.2.3).

BOX 4.2 Casting a shadow: Productivity in formal and informal firms (continued)

FIGURE B4.2.3 Labor productivity differential of formal firms with and without informal competition

On average, labor productivity in formal firms that face informal competition is only three-quarters of that of firms that do not face informal competition, after controlling for firm characteristics. Better business climates and governance and more advanced economic development can narrow this productivity differential.

A. Formal firms reporting competition from informal firms: By firm sector

B. Labor productivity differential of formal firms with and without informal competition: By intensity

C. Labor productivity differential of formal firms with and without informal competition: By level of development

D. Labor productivity differential of formal firms with and without informal competition: By business climate indicator

Sources: World Bank; World Bank (Enterprise Surveys).

A. Figures show the shares of formal firms.

B.-D. Based on coefficient estimates from table 4.5. It shows the results from an OLS regression with labor productivity as dependent variable, proxied by annual sales (in 2009 U.S. dollars) per worker. Sample of World Bank's Enterprise Surveys collected during 2007-14, including 4,036 informal firms and 7,558 formal firms in 18 countries. Whiskers show the corresponding ± 2 standard errors.

B. Figure shows log productivity differential between formal firms facing informal competition and formal firms not facing informal competition. "Maximum informal competition" assumes that all firms in a cell face informal competition. "Average informal competition" assumes that 55 percent of firms in a cell face informal competition.

C.D. Figure shows log productivity differential between formal firms facing informal competition and formal firms not facing informal competition (conditional on development and institution). Assumes that 55 percent of firms in a cell face informal competition. Each bar shows average labor productivity of the median country in the top ("highest quartile") or bottom ("lowest quartile") quarter of countries in terms of GDP per capita (C), control of corruption (D), ease of doing business (D) or business freedom index (D).

BOX 4.2 Casting a shadow: Productivity in formal and informal firms (continued)

- *Development.* Two groups of economies in the sample were examined: those economies with per capita income in the highest quartile in the sample and those in the lowest quartile. In formal firms that face informal competition in the average economy in the highest quartile of per capita incomes, labor productivity is only 14 percentage points less than in formal firms that do not face such competition. In contrast, on average in economies in the lowest quartile of per capita incomes, labor productivity in formal firms facing informal competition is 30 percent less than in those firms that do not face such competition.
- *Control of corruption.* Again, two groups of economies were examined: those in the quartile of economies with the strongest control of corruption and those in the quartile with the weakest control of corruption. In economies with the strongest control of corruption, on average, labor productivity in formal firms that face informal competition is only 22 percentage points less than formal firms that do not face such competition, whereas in the economies with the weakest control of corruption, this differential grows to 35 percent.
- *Ease of doing business.* Similarly, the labor productivity differential between formal firms that face informal competition and those that do not might halve (to 21 percent) if an economy like Angola (in the quartile of economies with the most difficult business climates) were to improve its business climate to the level of an economy like North Macedonia (among the economies with the most conducive business climates).

Robustness tests. The impact of informal competition on formal firm productivity is robust to alternative specifications. In particular, it is robust to controlling for characteristics that make the underreporting of output difficult (Amin and Okou 2020).

Conclusion

The productivity gap between informal and formal firms is substantial in EMDEs, averaging 75 percent in a sample of 18 EMDEs between 2007-14. Competition from informal firms also appears to weigh on the productivity of exposed formal firms: the productivity of formal firms that compete with informal firms is only three-quarters that of formal firms that do not compete with informal firms, after controlling for other firm characteristics. Improvements in the business climate, and economic development more broadly, can mitigate some of these negative productivity spillovers from informal to formal firms.

Enterprise Surveys for 2010-18, more than one-third of firms in the average EMDE with above-median informality identified access to finance as a major constraint—9 percentage points higher than in the average EMDEs with below-median informality—and a need to resort to internal finance to fund investment (figure 4.3). On average, three out of four firms in EMDEs with above-median informality depend on internal finance for investment, and only one out of five firms can utilize bank funds to finance their investment needs. Poor access to public services and markets also discourages entrepreneurs from entering the formal sector (Oviedo, Thomas, Karakurum-Özdemir 2009). In EMDEs with above-median employment informality, support for small and medium-sized enterprises (SMEs), such as access to business infrastructure and physical infrastructure, is significantly poorer than in EMDEs with below-median employment informality.⁸

Social safety net. In EMDEs, access to social security programs is often limited for informal workers (Medina and Schneider 2018; WIEGO 2019). As a result, in EMDEs with above-median output informality, only about 4 percent of the population are covered by social security programs such as unemployment insurance—about two-thirds of the level in EMDEs with below-median informality (figure 4.4). Without the ability to fall back on social safety nets and with limited personal savings, informal workers are vulnerable to adverse shocks, which can tip them into poverty. For example, in the one-third of EMDEs with the most pervasive informality, large health care expenses could impoverish more than one-third of households, which is 15 percentage points more than in the one-third of EMDEs with the least informality (box 2.1).

Distorted incentives. In weak institutional and regulatory environments, informal activity can perpetuate and deepen institutional weaknesses.⁹ For example, high taxation and heavy-handed regulation will increase firms' incentives to avoid taxation and regulatory compliance by remaining informal.¹⁰ Excessive labor regulations will encourage informal employment by increasing the cost of formal employment.¹¹ Corruption and rent-seeking bureaucracies will increase firms' incentives to avoid interaction with the state by remaining informal (Choi and Thum 2005; Friedman et al. 2000; Sarte 2000).¹² Governments may strategically design and implement systems of poor governance to promote informality for the poor as an alternative redistributive strategies (Marjit, Mukherjee, and Kolmar 2006). But poor governance stymies development.

⁸ Business infrastructure refers to the presence of property rights, commercial, accounting, and other legal and assessment services and institutions that support or promote SMEs.

⁹ Conversely, access to productivity-enhancing public goods, such as electricity and the legal system, can raise the share of formal production (Mendicino and Prado 2014).

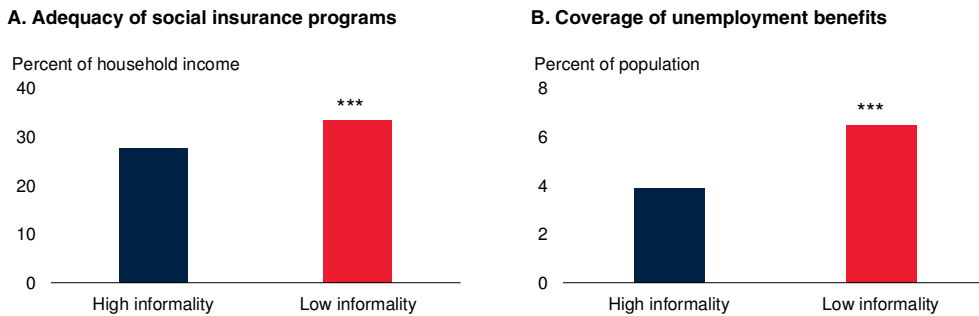

¹⁰ See Amaral and Quintin (2006); Auriol and Warlters (2005); D'Erasmus and Moscoso Boedo (2012); Dabla-Norris et al. (2018); Kanbur (2017); Ihrig and Moe (2004); Prado (2011); and Ulyseas (2018).

¹¹ See, for instance, Loayza (2016); Oviedo, Thomas, and Karakurum-Özdemir (2009); and Rauch (1991).

¹² In turn, widespread informality incentivizes government officials to impose excessive regulations that confers on them the power to collect bribes in return for providing permits (Shleifer and Vishny 1993).

FIGURE 4.4 Access to social benefits

Limited access to social protection programs makes informal workers more vulnerable during economic downturns.

Source: World Bank (World Development Indicators).

A.B. Bars are group means calculated for emerging market and developing economies with “high informality” (above-median DGE-based informal output in percent of GDP) and those with “low informality” (with below-median DGE-based informal output measure) over the period 1990-2018. DGE-based informal output are dynamic general equilibrium model-based estimates. Adequacy of social insurance programs is measured in percent of total welfare of beneficiary households. *** indicates group differences are not zero at 10 percent significance level.

Lack of resilience against the COVID-19 pandemic. The COVID-19 pandemic has exacerbated these development challenges (box 2.1). The global recession caused by the pandemic hit firms and workers in the informal sector particularly hard. Lockdowns have had a particularly disruptive effect on services activities involving human interaction, where informal firms are common, and have thus hit informal employment particularly hard. Large-scale fiscal support implemented in 2020 primarily targeted formal workers and formal firms, with limited support for informal workers or firms (chapter 2; World Bank 2020a). The unprecedented surge in unemployment caused by the global lockdown after the pandemic disproportionately affected jobs in low-value-added services with a large presence of informal jobs (Al Masri, Flamini, and Toscani 2021). A portion of job losses in the service sector may be permanent (Autor and Reynolds 2020; Zenker and Kock 2020).

Informality and economic correlates

A large empirical literature has documented the links between informality and poor economic conditions. In particular, a large informal economy is associated with lower per capita incomes, greater poverty, less financial development, limited trade openness, and weaker output growth. These indicators differ significantly between EMDEs with high and low informality (figure 4.5).

Methodology. The next sections rely on a comprehensive literature review as well as several empirical approaches to identify and illustrate the main correlates of informality. The data is drawn from the database detailed in chapter 2 and includes data for up to 160 EMDEs and 36 advanced economies for 1990-2018. First, a descriptive statistical approach is used. The sample of more than 122 EMDEs for 1990-2018 is split into

FIGURE 4.5 Informality and economic correlates

Lower GDP per capita, lower labor productivity, and greater poverty, but also better-shared, prosperity tend to be found in countries with higher informality.

Note: EMDEs = emerging market and developing economies; DGE = dynamic general equilibrium. “High-informality” (“Low-informality”) are EMDEs with above-median (below-median) DGE-based estimates of informal output (in percent of official GDP). *** indicates group differences are not zero at 10 percent significance level.

A. “GDP per capita” is in thousands of 2010 U.S. dollars, “Access to credit” is domestic credit to the private sector in percent of GDP, and “Human capital” is measured as average years of schooling. Data are for EMDEs over the period 1990-2018

B-D. Simple group averages over the period 1990-2018 for countries with higher informality (above median) and those with lower informality (below median) are shown in bars. EMDE averages over the period 1990-2018 are shown in orange lines.

B. Labor productivity is proxied by output per employment in thousands of 2010 U.S. dollar.

C-D. “Per capita income of bottom 40 percent” measures the annualized average growth of per capita real survey mean consumption or income for the bottom 40 percent of population.

those with above-median and below-median shares of informality by output (DGE-based estimates) and by employment (proxied by self-employment shares, see table 4.12; for other measures of informality, see table 4.13). Average development outcomes for these two groups are then compared provided that differences between the two groups are statistically significant. In the following sections, results are obtained using output informality, unless otherwise specified. The findings are robust to using employment informality, to the use of alternative definitions of informality or to using a regression that differentiates between quartiles of economies by informality (tables 4.14-4.15). These comparisons examine each correlate of informality individually. There is no presumption of causality going either from development to informality or vice versa.

BOX 4.3 Informality, poverty, and income inequality

Economies with greater informality also feature more poverty and greater income inequality. The coincidence of informality, poverty, and income inequality partly reflects wage differentials between formal and informal employment and the presence in those EMDEs where informality is more prevalent of weaker fiscal positions, social safety nets, and growth. Declines in informality have been associated with poverty reduction but not systematically with declines in income equality.

Introduction

Prevalence of informality is associated with persistent poverty and income inequality.^a This may reflect higher wages for formal than informal workers and more limited income redistribution in EMDEs with widespread informality. Limited redistribution, in turn, in part reflects a lack of fiscal resources; inefficient or inadequate tax and social security systems; burdensome regulations and taxation; and relatively slow economic growth.^b The association with inequality has been noted especially in poorer countries (Elgin and Elveren 2019; Dell’Anno 2016); other researchers have found an association with increases in income inequality (for instance, Mishra and Ray 2010; Rosser, Rosser, and Ahmed 2000).^c

The COVID-19 pandemic has led to an increase in global poverty for the first time in decades (World Bank 2020b, 2021). It has hit informal firms and informally employed workers particularly hard, in part because they struggled to adjust to digital operations and to access government support schemes (box 2.1; Yoshida, Narayan, and Wu 2020). Meanwhile, because of severe economic contractions in the formal sector, the share of informal activity is likely to have increased as a result of the pandemic.

Against this backdrop, this box explores and quantifies the relationships between informality and poverty and income inequality by addressing the following questions:

- How strong is the association between informality and poverty or income inequality?

Note: This box was prepared by Sergiy Kasyanenko.

a. For cross-country studies, see Devicienti, Groisman, and Poggi (2009); Fields (2019); Fields and Pieters (2018); Gasparini and Tornaroli (2007); ILO (2018b); and World Bank (2019, 2020b).

b. See World Bank (2019, 2020b); Perry et al. (2007); Besley and Persson (2014); and Ordóñez (2014).

c. Country level studies often find that higher informality is associated with greater income inequality (Amarante, Arim, and Yapor 2016; Ariza and Montes-Rojas 2017; Docquier and Ifikhar 2019).

BOX 4.3 Informality, poverty, and income inequality (continued)

- Which factors could account for the correlation between informality and poverty or income inequality?
- Is declining informality associated with reductions in poverty and inequality?

This box finds that more pervasive informality is associated with higher poverty and income inequality in EMDEs and that high pre-existing informality may substantially slow subsequent poverty reduction and improvements in shared prosperity. Economies with high informality have slower output and labor productivity growth, holding back poverty reduction and income growth for low-income workers. Declines in informality turn out to be significantly associated with poverty reduction—but not with reductions in income inequality. The link between declining informality and poverty reduction is weaker in regions that started with above-average poverty levels, such as South Asia (SAR) and Sub-Saharan Africa (SSA).

This box contributes several new findings to the literature. It uses a large sample of EMDEs to quantify the correlation between changes in informality and changes in poverty and income inequality over time. The existing literature predominately focuses on country-level studies of poverty and informality.^d Berdiev, Saunoris, and Schneider (2020) find a positive association between the *levels* of poverty and informality in a sample of over 100 countries. This box explores the links between *changes* in informality and poverty or inequality over time, as well as the associations between the levels of these variables. It shows that declines in poverty tend to follow declines in informality, while income inequality remains largely stable.

Cross-country patterns in informality, poverty, and income inequality

A large empirical and theoretical literature has documented the associations between informality and poverty and income inequality. This box updates and extends previous studies.

Methodology. The sample of 122 EMDEs for 1990-2018 is split into those with above-median and below-median shares of output informality. Output informality is measured by DGE-based estimates of informal output in percent of official GDP. Average indicators of poverty and income inequality for these two groups are tested for statistically significant differences. Cross-economy regressions are estimated for the associations between informality and poverty or

d. See Amuedo-Dorantes (2004); Canelas (2019); Devicienti, Groisman, and Poggi (2009); Kim (2005); and Nazier and Ramadan (2015b).

BOX 4.3 Informality, poverty, and income inequality (continued)

income inequality, controlling for the differences in overall development (proxied by real GDP per capita; table 4.6). Similar regressions are also conducted for the relationships between the changes in poverty and income inequality over time and pre-existing levels of informality (annex 4B).

Poverty and informality. On average between 1990 and 2018, more than one in four people in EMDEs with above-median informality lived below the international extreme poverty line of \$1.90 per day (in 2011 U.S. dollars)—about five times as many as in EMDEs with below-median informality (figure B4.3.1). Workers in the informal sector face higher risks of impoverishment than their formal counterparts (Chen, Vanek, and Heintz 2006).

Income inequality and informality. Between 2009 and 2018, average consumption or income of the poorest 40 percent of the population in EMDEs with above-median informality amounted to about \$4 per day (measured in 2011 PPP terms)—statistically significantly below the \$5-6 per day average in EMDEs with below-median informality. Over the same period, income growth for the bottom 40 percent of the population outstripped average income growth by significantly more in EMDEs with below-median informality than in EMDEs with above-median informality. This suggests that progress in improving shared prosperity was more rapid in EMDEs with below-median informality than in those with above-median prosperity.

Channels of interaction

Several channels have been suggested for links between informality, poverty, and inequality: wage differentials between formal and informal workers; less redistributive and effective fiscal policies, including poorer coverage of social safety nets, in more informal economies; and slower economic growth in more informal economies (Besley and Persson 2014; Perry et al. 2007; World Bank 2019, 2020a).

Informality and fiscal indicators. Pervasive informality erodes the tax base and constrains governments' ability to provide public services, conduct countercyclical policies, service debt, and implement inequality-reducing redistributive measures (Besley and Persson 2014; Ordóñez 2014). Government revenues in EMDEs with above-median informality were 5-12 percentage points of GDP below those in EMDEs with below-median informality and were tilted towards trade taxes and away from income taxes (chapter 6). Higher informality was also associated with statistically significantly lower public spending on education and health, contributing to the slower accumulation of human capital and income convergence.

BOX 4.3 Informality, poverty, and income inequality (continued)**FIGURE B4.3.1 Informality and poverty and income inequality**

More pervasive informality is associated with significantly more prevalent poverty and higher income inequality. A reduction in informality is positively associated with poverty alleviation, albeit the strength of this link varies across EMDE regions. The link between formalization and improvement in income inequality is largely missing.

A. Change in poverty by EMDE region**B. Change in output informality by EMDE region****C. Extreme poverty above 5 percent across EMDE regions****D. Output informality above 35 percent across EMDE regions****E. Output informality and poverty and income inequality****F. Elasticities of poverty and shared prosperity to output informality**

Source: World Bank (World Development Indicators).

Note: Data for the period 1990-2018. Informality is proxied by dynamic general equilibrium model-based estimates on informal output in percent of official GDP. Low/high informality indicates informality below/above median output informality. "Poverty" refers to income below the \$1.90 per day poverty line. "Shared prosperity" refers to the income share of the bottom 40 percent of population. EAP = East Asia and Pacific; ECA = Europe and Central Asia; EMDEs = emerging market and developing economies; LAC = Latin America and the Caribbean; MNA = Middle East and North Africa; SAR = South Asia; SSA = Sub-Saharan Africa.

A.B. Median change from 1990-99 to 2010-18. Whiskers show 25-75 percentile range.

C.D. Based on average poverty/output informality during the period. Sample includes 122 EMDEs.

E. Averages over the period 1990-2018 for countries with high and low informality. The world averages are shown in orange lines. *** indicates group differences are significant (at least at 10 percent level).

F. Bars show coefficient estimates from regressions of changes in poverty (table 4.7; and changes in shared prosperity in table 4.8) on changes in output informality. A positive coefficient indicates that a decline in output informality reduces (increases) poverty (income inequality). Whiskers show 90 percent confidence intervals.

BOX 4.3 Informality, poverty, and income inequality (continued)

Greater reliance on indirect taxation in more informal economies made the tax system less progressive than systems based more on direct taxation. The reduction in income inequality due to taxes and transfers (i.e., the difference between Gini coefficients before and after taxes and transfers) was about 6 Gini points on average in EMDEs with above-median output informality—statistically significantly less, by 13 Gini points, than in EMDEs with below-median output informality.

Informality and social safety nets. Limited government spending envelopes and poor spending efficiency also constrain the coverage of social protection programs (Dabla-Norris, Gradstein, and Inchauste 2008; Joshi, Prichard, and Heady 2014; Ordóñez 2014). During 1998-2018, only one-third of people in the poorest quintile of the population in EMDEs with above-median employment informality were covered by social protection and labor market programs—considerably less than the more than half in EMDEs with below-median employment informality. In EMDEs with above-median informality, the average daily transfer per capita (in PPP terms) was one third less than in EMDEs with below-median informality.

In EMDEs with above-median informality, social protection and labor programs lowered the Gini coefficient by 2-4 points, significantly less than the 8-11-point reduction in EMDEs with below-median informality. Social protection and labor programs accounted for only about one-tenth of poverty reduction in EMDEs with above-median informality during 2009-2018, again significantly less than the one-quarter of poverty reduction in EMDEs with below-median informality.

Worker earnings differentials. A formal wage premium—systematically higher wages in the formal than informal sector—is a long established finding in the literature. In a meta-analysis of empirical studies on formal wage premiums, wages in the formal sector were found to be 19 percent above informal wages on average (box 4.1).

Over-time patterns in informality, poverty, and inequality

While informality is typically accompanied by poverty, the evidence that informality reduction is associated with lower poverty or income inequality is less conclusive. In some cases, the informal sector provides a critical source of income for the poorest and helps ward off poverty during adverse events (Rogan and Cichello 2020). While policies to reduce informality in EMDEs have often been complemented by poverty-alleviation initiatives such as income-support or unemployment protection programs, these initiatives can fail to reach the very poorest groups and can create their own disincentives for formal employment (Bloeck, Galiani, and Weinschelbaum 2019; Gasparini, Haimovich, and Olivieri

BOX 4.3 Informality, poverty, and income inequality (continued)

2009). Declines in informality and poverty often coincide with rapid economic growth, which can raise income inequality when structural factors that widen income disparities (such as urbanization and demographic change) are not offset by other policies (for example, tax and expenditure reforms; Jain-Chandra et al. 2018).

Methodology. A similar methodology to that used by Dollar and Kraay (2002) and Dollar, Kleineberg, and Kraay (2013) is applied here to investigate the link between within-country changes in informality over time and changes in poverty and inequality reduction (annex 4B). Income inequality is proxied by the Gini coefficient or the share of income of the poorest 40 percent of the population (“bottom 40 percent”) within each country. The sample of country-year observations is assembled by starting with the first available observation for each country and selecting all available consecutive observations that are at least five years apart. This approach yields about 428 economy-year pairs over the period 1990-2018 for 32 advanced economies and up to 119 EMDEs. A median distance between observations is 5.5 years for EMDEs and 5 years for advanced economies. A cross-country fixed-effects regression estimates the changes in poverty and inequality associated with changes in informality.

Evolution of informality. Output and employment informality have declined steadily over the past three decades, but with considerable heterogeneity across and within EMDE regions (figure B4.3.1). In the median EMDE, output informality contracted by 4 percentage points of GDP between 1990-99 and 2010-18. It declined most in SAR (by about 10 percent of official GDP) and East Asia and the Pacific (EAP, by about 6 percent of official GDP). In Europe and Central Asia (ECA) and Latin America and the Caribbean (LAC), output informality fell by about 3.5 and 2 percentage points of official GDP, respectively.

Evolution of poverty and income inequality. Most EMDEs saw a substantial reduction in the share of population living below the \$1.90 a day poverty line, although the pace of poverty reduction was slow in SSA (World Bank 2020b). Progress in improving shared prosperity was more heterogeneous across regions. While the share of income captured by the bottom 40 percent of population increased by about 2 percentage points from 1990-99 to 2010-18 in a median EMDE, it did not change much in EAP and SAR despite a notable reduction in poverty.

Decline in informality and poverty reduction. The regression results suggest that a 1-percentage-point reduction in output informality in EMDEs has been associated with a 0.6-percentage-point decrease in the share of population living in extreme poverty (on less than US\$1.90 a day in 2011 U.S. dollars) and a

BOX 4.3 Informality, poverty, and income inequality (continued)

significant decrease in the share of the population living on less than US\$3.20 a day (figure B4.3.1; table 4.7).

Decline in informality and improvements in income inequality. Consistent with the literature on income inequality and economic development, no strong or statistically significant relationship was found here between declines in informality and changes in inequality indicators (Adams 2003; Banerjee and Duflo 2003). A reduction in informality may play only a small role in inequality reduction partly because workers who transition from informal to formal jobs are already in the upper tail of the wage distribution, such as informal workers in formal firms (Messina and Silva 2021). Unlike in poverty regressions, where GDP growth and reductions in informality are strongly associated with poverty reduction, neither economic growth nor declines in informality appear to be statistically significantly correlated with changes in shared prosperity indicators (table 4.8).

Conclusion

Economies with higher informality also tend to have higher poverty and greater income inequality. Several forces contribute to this pattern. More constrained public spending envelopes in EMDEs with widespread informality limit governments' ability to provide public services, resulting in more limited coverage and adequacy of social security programs. Workers in the formal economy earn, on average, about a fifth more than workers in the informal economy; this earnings gap contributes to the higher levels of poverty and income inequality in EMDEs with more pervasive informality. Without establishing the causal relationship between changes in informality and changes in poverty or income inequality, the box finds that reductions in informality were typically accompanied by poverty reduction, but not by reductions in income inequality. The confirmation of causal relationship between informality and poverty (and income inequality) presents an area for future research.

To identify the most robust correlates of informality among this large menu, this chapter conducts a Bayesian Model Averaging (BMA) estimation. The large number of (often inter-correlated) correlates of informality gives rise to concerns about model uncertainty (annex 4C). The BMA approach addresses model uncertainty formally—by recognizing that the identity of the true model is unknown and by combining various sets of potential correlates of informality, ranging from economic development to infrastructure quality. This approach also addresses concerns about omitted variables in the bilateral correlations depicted in the stylized facts.

Lack of development. Higher informality is associated with lower levels of per capita income and other measures of economic development.¹³ For both output and employment informality, GDP per capita in EMDEs with below-median (“low”) informality is about four times that in EMDEs with above-median (“high”) informality (figure 4.5).¹⁴ Since informal activity is concentrated in services and agriculture, more manufacturing-based and more urban economies feature less informality. On average, about three fifths of the population in EMDEs with below-median informality, but only two fifths of the population in EMDEs with above-median informality, resides in urban areas. Past studies also show that more widespread informality has been associated with slower growth of output and investment and—in some studies—labor productivity (Perry et al. 2007; World Bank 2019).¹⁵

Poverty. Greater prevalence of informality is associated with greater prevalence of extreme poverty (figure 4.5; World Bank 2019). In 2000, the share of the population living on less than \$1.90 a day was 44 percent in EMDEs with above-median informality—more than twice the share in EMDEs with below-median informality. In 2018, one in four people remained in extreme poverty in EMDEs with above-median informality, while fewer than one in ten people were in extreme poverty in EMDEs with below-median informality.

Financial development. Financial development, which reduces external financing costs, can incentivize entrepreneurs to join the formal sector and comply with tax obligations.¹⁶ EMDEs with above-median informality significantly lag in financial development behind EMDEs with below-median informality (figure 4.3; chapter 6). People in EMDEs with below-median informality have access to significantly more commercial bank branches, automated teller machines (ATMs), and credit facilities than those in EMDEs with above-median informality. About half of the population in EMDEs with below-median informality hold an account at a financial institution or use a mobile money service, which is significantly higher than the share in EMDEs with above-median informality, by about 18 percentage points. In financially less developed EMDEs, a higher share of entrepreneurs rely more on internal funding for starting, operating, or expanding their firms (figure 4.3; Epstein and Shapiro 2017; Farazi 2014).

International trade and financial openness. While greater financial openness has been associated with lesser informality, the link between trade openness and informality is unclear. Higher capital account openness was associated with less output and

¹³ See La Porta and Shleifer (2014) and Loayza, Servén, and Sugawara (2010). However, there is also empirical evidence that the relationship between the extent of informality and the level of development has a U shape, with the informal economy tending to expand again (or at least to not shrink further) when economic development surpasses a certain threshold (Wu and Schneider 2019).

¹⁴ Median informality amounts to about 36 percent of GDP for DGE-based informal output and 43 percent of total employment for self-employment.

¹⁵ Also see D’Erasmus and Moscoso Boedo (2012); Docquier, Müller, and Naval (2017); and Medina and Schneider (2019).

¹⁶ See Blackburn, Bose, and Capasso (2012); Capasso and Jappelli (2013); D’Erasmus and Moscoso Boedo (2012); and chapter 6.

employment informality (World Bank 2019). That said, the impact of major trade liberalizations on informality has varied across countries, differed between the short- and the long-term, and between workers and firms (Dix-Carneiro and Kovak 2017; Fugazza and Fiess 2010; Goldberg and Pavcnik 2003). Several studies show informality declining after trade liberalization.¹⁷ In the presence of labor market rigidities, however, informal employment may rise in the short term after trade liberalization but not necessarily in the long-term.¹⁸ In Brazil and Peru, trade liberalization and increased import competition were associated with increases in informality as informal firms exited and formal firms increasingly hired informal workers (Cisneros-Acevedo, forthcoming) or workers increasingly worked informally (Dix-Carneiro and Kovak 2019).

Informality and institutions

More informality is also associated with lower government revenues and expenditures, less effective public institutions, more burdensome tax and regulatory regimes, and weaker governance (e.g., Dabla-Norris, Gradstein, and Inchauste 2008; Enste and Schneider 1998; World Bank 2019).¹⁹

Government revenues and expenditures. On the basis of the various measures of informality, government revenues in EMDEs with above-median informality were, on average, 5-12 percentage points of GDP below those with below-median informality during 2000-2018 (figure 4.6). The composition of tax revenues is also tilted toward trade taxes in economies with more pronounced informality, making the tax system less progressive but facilitating tax collection when income underreporting is widespread. Similarly, in EMDEs with more pervasive informality, government expenditures were 5-10 percentage points of GDP lower than in those with less informality.

Such constrained government spending is reflected in more limited provision of government services, contributing to poorer human development outcomes (Gaspar et al. 2019). During 2000-18, EMDEs with above-median informality spent about 2 percent of GDP on health, which was 1 percentage point of GDP lower than in EMDEs with below-median informality (figure 4.6). The average number of pupils per teacher in primary schools was about 35 in EMDEs with above-median informality—significantly higher, by eight student per teacher, than in EMDEs with below-median informality. Access to medical resources, such as physicians and nurses, was also significantly more limited in EMDEs with a more pervasive informal sector (World Bank 2020a).

Regulatory burdens. Both empirical and theoretical studies suggest that heavier regulatory (or administrative) burdens are associated with greater informality (figure

¹⁷ See Boly (2018); Goldberg and Pavcnik (2004, 2007); and McCaig and Pavcnik (2018).

¹⁸ See Attanasio, Goldberg, and Pavcnik (2004); Bosch, Gofii-Pacchioni, and Maloney (2012); Goldberg and Pavcnik (2003); Ponczek and Ulyssea (2018); and World Bank (2019).

¹⁹ Access to the court system can also encourage formal production (Mendicino and Prado 2014; Schneider, Buehn, and Montenegro 2010).

FIGURE 4.6 Informality, fiscal indicators, and institutional quality

Informality is associated with lower government revenues and expenditure capacity, hindering economies' abilities to provide health and education services. EMDEs with above-median informality tend to have more burdensome regulations and weaker governance.

A. Differential in government revenues between EMDEs with above- and below-median informality

B. Government spending and informality

C. Access to education resources

D. Access to medical resources

E. Regulatory burdens

F. Governance

Note: Informality is proxied by dynamic general equilibrium (DGE)-based estimates of informal output in percent of GDP. Data for emerging market and developing economies (EMDEs). "High-informality" ("Low-informality") are EMDEs with above-median (below-median) DGE-based informal output measures. *** indicates group differences are not zero at 10 percent significance level.

A. Differences in percentage points of GDP between the average fiscal indicators among EMDEs with above-median and below-median informality are in bars, with corresponding 90 percent confidence intervals shown by whiskers. All fiscal indicators and informality measures are 2000-18 averages for EMDEs with populations above 3.5 million (several oil-exporting outliers are dropped).

B. Simple group averages of public expenditure over the period 2000-18. Overall expenditures are for EMDEs with population above 3.5 million.

C. Simple group averages are in bars over the period 1990-2018. "Pupil-teacher ratio" measures the average number of pupils per teacher in primary school. "Trained teachers" captures the percentage of primary school teachers who have received the minimum organized teacher training (pre-service or in-service) required for teaching in a given country.

D. Simple group averages over the period 2010-18. Two outlier countries, Belize and Belarus, are excluded from the sample.

E.F. Simple group averages are in bars over the period 1990-2018. Doing business score ranges from 0 (lowest performance) to 100 (best performance). Data for business registration costs are for 2003-18 (2010-18 for doing business scores). "Bureaucracy quality," "Control of corruption," and "Law and order" are from ICRG, with higher values corresponding to better outcomes.

4.6).²⁰ Over the period 2010-18, the average ease of doing business score for EMDEs with below-median informality (by DGE estimates) was higher by 7 points—two-thirds of a standard deviation—than for EMDEs with above-median output informality.²¹ Similarly, the average cost of business start-up procedures amounted to 92 percent of gross national income (GNI) per capita in EMDEs with above-median output informality, significantly higher than in EMDEs with below-median output informality, by about 65 percentage points.

Governance. A large literature has documented the coincidence of poor governance with pervasive informality in many EMDEs, especially in Latin America and the Caribbean (LAC) and Europe and Central Asia (ECA).²² On average, EMDEs with above-median informality have had significantly poorer-quality bureaucracies, by about one standard deviation in terms of the ICRG's rating, than EMDEs with below-median informality.²³ Similar differences pertain to the control of corruption and law and order. There are also country cases suggesting that informality declined faster in the presence of greater improvements in governance and better initial governance (World Bank 2019). For example, in Georgia, during 1996-2016, the transition to a market economy brought significant improvements in government effectiveness, control of corruption, and rule of law. With output growth averaging about 6 percent per year, the share of informal output fell from 66 percent to 57 percent of GDP, and the share of informal employment in total employment fell by a similar magnitude (World Bank 2019).

Informality and human development-related SDGs

Greater informality is associated with weaker human development outcomes. People living in EMDEs with more widespread informality suffer from a greater prevalence of hunger, poorer health and education, greater gender inequality, and lower human capital (figure 4.7; Docquier, Müller and Naval 2017; Maloney 2004).

Hunger. EMDEs with more pervasive informality fared far worse during 1990-2018 in terms of the hunger-related SDGs than those with less pervasive informality. The share of the population suffering from stunting and wasting was significantly higher in EMDEs with above-median informality: more than a quarter of children under five years of age in EMDEs with above-median informality suffered from stunting, with

²⁰ See Bruhn (2011); de Mel, McKenzie, and Woodruff (2013); Perry et al. (2007); Rocha, Ulyssea, and Rachter (2018); and Ulyssea (2010).

²¹ Similarly, the Heritage Foundation's business freedom index was about three-quarters of a standard deviation higher in countries with below-median output informality than in countries with above-median informality.

²² Sarte (2000) suggests that firms operate in the informal sector to avoid rent-seeking bureaucrats. Dreher and Schneider (2010) and Choi and Thum (2005) report an association between higher informality and weaker law and order and control of corruption. Dabla-Norris, Gradstein, and Inchauste (2008) show that the quality of the legal framework is important in determining the size of the informal sector.

²³ The measures of institutional quality used here are taken from the International Country Risk Guide (ICRG 2014). A higher value indicates better institutional quality. In the case of bureaucracy quality, high points are given to countries where the bureaucracy has the strength and expertise to govern without drastic changes in policy or interruptions in government services.

FIGURE 4.7 Informality and human development-related SDGs

EMDEs with more pervasive informality face more severe challenges in progressing toward human development-related SDGs. People in EMDEs with more informality tend to suffer more from hunger, poor health and education, and gender inequality.

A. Hunger and informality

B. Agricultural productivity and informality

C. Health outcome indicators and informality

D. Educational attainment, gender equality, and informality

Sources: Sachs et al. (2018); Sachs et al. (2020); World Bank (World Development Indicators).

Note: "High informality" ("Low informality") are emerging market and developing economies (EMDEs) with above-median (below-median) dynamic general equilibrium model-based informal output measure over the period 1990-2018. Figures show the latest available data. *** indicates that group differences are significant at 10 percent level.

A. Average shares of population (children under 5 years of age) that suffer from undernourishment (stunting) for corresponding country groups. Based on 144 EMDEs.

B. Agricultural productivity is measured as cereal yield (tons per hectare of harvested land). Based on 141 EMDEs.

C. Bars for group averages for the latest year available. "Maternal mortality" is measured in per 10,000 live births. "Under 5 mortality" is measured in per 1,000 live births. "Death rate from pollution" are age-standardized death rates (per 100,000 persons) due to household and ambient (outdoor) pollution. "Life expectancy" at birth is measured in years. Based on up to 153 EMDEs.

D. Bars for group averages for the latest year available. "Net primary school enrollment" rate ("net primary schI enrI") is measured in percentage points. Mean years of schooling are measured in years (in multiplier of 10; taken from Sachs et al. 2018). "Literacy rate" of 15-24 years old is measured in percent of population. "Female years of schooling" is measured in percent of male schooling years. "Family planning" measures the percentage of women reporting having their family planning needs attended. "Female informal workers" captures the percent of female workers informally employed among all female workers.

more than 15 percent of the population being undernourished (Sachs et al. 2020). Both shares are significantly higher than in EMDEs with below-median informality, by about 10 percentage points. The higher prevalence of hunger in EMDEs with above-median informality is partly explained by lower agricultural productivity. On average, the cereal yield in EMDEs with above-median informality is less than two-thirds of the yield in EMDEs with below-median informality (figure 4.7).

Health. People in EMDEs with more widespread informality face poorer health outcomes. According to the latest available data, in 2016, the average life expectancy at birth in EMDEs with above-median informality was around 67 years, which is about 6 years shorter than in EMDEs with below-median informality. Both the maternal mortality rate and the mortality rate of children under 5 years old in EMDEs with above-median informality were nearly twice the rates in EMDEs with below-median informality. In EMDEs with above-median informality, on average, about 133 deaths per 100,000 persons were caused by household air pollution and ambient pollution, which is significantly higher than in EMDEs with below-median informality by more than 50 deaths per 100,000 persons.

Education. Access to education is less available in EMDEs with more pervasive informality (Docquier, Müller, and Naval 2017). On average in EMDEs with above-median informality, people spent less than 7 years in schooling, compared with 8-9 years in EMDEs with below-median informality. Less than 85 percent of the population aged 15-24 years in EMDEs with above-median informality is literate—more than 10 percentage points less than the population in EMDEs with below-median informality.

Gender equality. Female workers make up a disproportionate share of workers in the informal sector (Bonnet, Vanek, and Chen 2019; ILO 2018b). In EMDEs with above-median employment informality, 87 percent of employed women work in the informal sector, which is about three-quarters higher than in EMDEs with below-median employment informality (table 4.12). In South Asia (SAR) and Sub-Saharan Africa (SSA), the regions where informality is most pervasive, about 80 percent of female workers in the non-agricultural sector are informally employed (UN Women 2016). In LICs, up to 92 percent of all employed women work in the informal sector (ILO 2018b; OECD/ILO 2019). Working in the informal sector exposes female workers to low remuneration, poor working conditions, and lack of or limited access to social protection and rights at work (ILO 2019; Otobe 2017).

EMDEs with more widespread informality are also associated with greater gender inequality in broader terms. The average years of schooling received by women in EMDEs with above-median informality are, on average, 20 percent less than the average years received by men, in stark contrast to EMDEs with below-median informality where no significant gender gap in schooling prevails. Only 55 percent of women in EMDEs with above-median informality have their family planning needs attended to, which is 10 percentage points lower than in EMDEs with below-median informality. In addition to factors such as traditional gender roles, lack of access to education and insufficient coverage of family planning needs constrain women's ability to participate in the formal sector (Malta et al. 2019).

Informality and infrastructure-related SDGs

More widespread informality is associated with poorer access to, and lower overall quality of, infrastructure, with causality running in both directions. Thus widespread informality tends to limit government revenue and hence public expenditure on

infrastructure but, conversely, poor access to infrastructure can discourage firms or workers from joining the formal sector and engaging with the government (Perry et al. 2007). Infrastructure weaknesses create an additional obstacle to human capital accumulation and job creation, entrenching informality (Vorisek and Yu 2020). Lack of energy and communications infrastructure limits access to more and better job opportunities and slows productivity gains from digital technologies (Zaballos, Iglesias, and Adamowicz 2019). Poor transportation networks restrict factor mobility and market access, thus slowing productivity growth.²⁴ Weak within-city transportation networks prevent workers from accessing formal employment opportunities (Zarate 2019).

Sanitation and clean water. Greater informality is associated with more limited access to sanitation facilities and clean water (figure 4.8). In EMDEs with above-median informality, only around 55 percent of the population have access to basic sanitation services—about 30 percentage points fewer than in EMDEs with below-median informality. While almost all people in EMDEs with below-median informality have access to clean drinking water, this essential infrastructure service is only available to less than 80 percent of the population in EMDEs with above-median informality.

Access to energy and ICT infrastructure. Access to infrastructure services such as electricity, clean fuels, the internet, and mobile broadband is more limited in EMDEs with above-median informality. As shown by the latest available data, about one-third of people living in EMDEs with above-median informality lacked access to electricity, while almost all in EMDEs with below-median informality had such access. The share of the population with access to clean fuels in EMDEs with above-median informality is about half of the share in EMDEs with below-median informality. Access to the internet and mobile broadband was available to 30-40 percent of the population in EMDEs with above-median informality—less than three-fifths of the share in EMDEs with below-median informality.

Road access. Despite progress made in recent years, road access remains more limited in EMDEs with above-median informality. The latest data show that only around 15 percent of roads were paved in EMDEs with above-median informality—one-third of the share in EMDEs with below-median informality. This could in part reflect higher costs of road construction in EMDEs with more pervasive informal sectors: on average, road construction costs amounted to US\$ 0.6 million per km in EMDEs with above-median informality—significantly higher than the cost in EMDEs with below-median informality, by US\$ 0.2 million per km.

Finding the needle in the haystack: The most robust correlates

The analysis so far has considered individual correlates of informality in isolation. This section aims to identify the most robust correlates of informality via a Bayesian Model

²⁴ See Banerjee, Duflo, and Qian (2020); de Soyres, Mulabdic, and Ruta (2020); and Francois and Manchin (2013).

FIGURE 4.8 Informality and infrastructure-related SDGs

Higher infrastructure costs and lower quality of overall infrastructure are associated with more pervasive informality. EMDEs with above-median informality tend to have significantly less access to various types of infrastructure than those with below-median informality.

A. Quality of overall infrastructure

B. Access to clean water and sanitation

C. Access to energy

D. Access to ICT-related infrastructure

E. Access to roads

F. Road project costs

Sources: Sachs et al. (2018); Sachs et al. (2020); World Bank (Road Costs Knowledge System [ROCKS] database; World Development Indicators).

Note: "High informality" ("Low informality") are emerging market and developing economies (EMDEs) with above-median (below-median) dynamic general equilibrium (DGE)-based informal output, measured over the period 1990-2018. *** indicates group differences are significant at 10 percent level.

A. Bars show the average overall infrastructure quality for the latest year available. The index is taken from Sachs et al. (2018) and ranges from 1 to 7, with higher values representing better overall infrastructure quality. Based on 115 EMDEs.

B.-E. Bars show the group means for the latest year available. Based on up to 153 EMDEs.

F. Bars show group averages for the latest year available. Data are for 51 EMDEs (outliers, GIN, MWI, and PER, are dropped). "Unit cost (all projects)" excludes new 4-lane and 6-lane expressway projects as they cost much more than other projects and do not exist in EMDEs with above-median informality. Reconstruction is the most common road project by project number. Data are from the latest year available. Based on 77 EMDEs.

FIGURE 4.9 Results from Bayesian Model Averaging approach

A wide range of economic and institutional conditions, such as better governance, a more developed and diversified economy, and better human capital, are associated with less pervasive informality in EMDEs.

A. Effect of group correlates on the evolution of output informality

B. Probability of inclusion

Source: World Bank.

Note: Based on the panel regression result using Bayesian Model Averaging technique. In A, *** denotes that the signs of the estimated coefficients are the same for 90 percent of the model, conditional on inclusion of the variable. The dependent variable is the share of informal economy in GDP using dynamic-general-equilibrium-based estimates on informal output as a share of official GDP. From an unbalanced panel from 67 EMDEs and 5-year periods over 1998-2018. See annex 4C for details.

A. Predicted differences in the share of output informality for countries whose correlates differ by one standard deviation.

B. Probability of including at least one variable from the group to the regression (Posterior Inclusion Probability). The groups whose posterior inclusion probabilities exceeded the prior of 50 percent could be regarded as relevant.

Averaging (BMA) approach. The approach utilizes a large number of possible correlates that have been identified in the literature and reviewed in the previous sections. It recognizes the unknown nature of the true relationship between informality and various conditions and combines evidence from different models.

Methodology. Following Dieppe et al. (2020) and Durlauf, Kourtellos, and Tan (2008), independent variables that represent common concepts are grouped together to estimate their group marginal effects. The correlates of informality are sorted into seven groups, covering economic development, human capital, financial development, and governance (table 4.9). Analyses are carried out at the level of output informality, proxied by the share of informal output in GDP, while using the levels of correlates as independent variables (table 4.10). The results from a similar analysis using employment informality are broadly consistent (annex 4C). The sample comprises an unbalanced panel of 68 EMDEs, observed from 1998 to 2018 in five-year windows.

Results. The results are broadly consistent with existing studies about individual correlates. First, the posterior inclusion probabilities for several variable groups under consideration exceed 0.50 (figure 4.9). This finding suggests that most of these factors are related to the level of output informality. The group posterior inclusion probabilities (PIPs) are highest—near 1—for economic development, human capital, and governance, indicating these factors' particularly strong association with informality. The results indicate their stronger association with the level of output informality than other groups of variables.

Second, all the correlates are associated with the level of informality in the expected manner (figure 4.9). EMDEs with better governance, a more developed and less agriculture-oriented economy, and stronger human capital tend to have lower informality. In particular, informal output as a share of official GDP is significantly lower, by around 1-2 percentage points of GDP, if the EMDE has one-standard-deviation better governance, greater economic development, or larger human capital. In addition, tax burdens, measured as the share of government consumption or tax revenue in GDP, are significantly and negatively correlated with the size of output informality.

Conclusion

Pervasive informality is associated with a wide range of development challenges, from extreme poverty to lack of access to basic sanitation services. This chapter documented and quantified the wider gaps, relative to the SDGs, among EMDEs with greater informality. These shortcomings also make EMDEs with widespread informality particularly vulnerable to adverse global shocks, including the COVID-19 pandemic.

The wide range of correlates of informality suggests that informality is a phenomenon that reflects broad-based underdevelopment rather than a challenge that can be considered in isolation. Consequently, policy measures to address informality need to be equally broad-based. They include measures to enhance human capital and lift productivity, streamline regulations, and improve governance and the provision of public services and social safety nets. Policy options are discussed in detail in chapter 6.

Several areas for further development are worth exploring. First, the chapter does not demonstrate a causal link between informality and the various development outcomes. The exploration of causal relationships between informality and these outcomes, in either direction, is left for future studies. Second, due to data limitations, some variables, such as access to paved roads and bank account ownership, that are relevant to informality are not included in the current BMA analysis. Future studies can improve upon the work reported here by incorporating those variables. Third, future research could explore asymmetries in the challenges posed by informality. There may be interactions between country circumstances and worker or firm characteristics that can mitigate some of the challenges posed by informality. For firms, some of these interactions were explored in box 4.2 but other important interactions may yet come to light in future research.

ANNEX 4A Meta regression analysis

A random-effects model assumes that there is a distribution of true effects rather than a common fixed effect across studies (DerSimonian and Laird 1986). In particular, a study-specific estimate of the informal-formal wage gap has a sampling distribution $\hat{\theta}_i \sim N(\theta_i, \sigma^2)$, where σ^2 is the within study variance of the estimate due to a sampling error; while the true effect has the following distribution $\theta_i \sim N(\mu, \tau^2)$. Meta-analysis pools information across many studies to estimate μ and τ^2 , where τ^2 measure the degree of across-study variations.²⁵ The proportion of total variation in study estimates is equal to $I^2 = \tau^2 / (\tau^2 + \sigma^2)$ and reflects the impact of across-study heterogeneity (Higgins and Thompson, 2002). The meta-regression analysis (MRA) can be performed to associate this variation with any characteristics of the study or sample.

The MRA of estimated wage differentials between formal and informal jobs uses estimates of the wage gap drawn from each study as the dependent variable. The set of regressors, or moderator variables, includes study characteristics that are deemed consequential for the reported results, for example, identification and estimation methods, study design and data sources. This, in particular, helps clarify the diversity of research outcomes on the size of the informal-formal wage gap and identify the sensitivity of reported wage gaps to study-specific methods and data. A random-effects MRA is performed by estimating the following regression:

$$\hat{\theta}_i = \mu + \sum_j^k \alpha_j X_{ij} + \epsilon_i + \vartheta_i,$$

where $\hat{\theta}_i$ is a study-specific estimate of the informal-formal wage gap, ϵ_i is a sampling error with a standard deviation that may vary across studies, ϑ_i is an error term reflecting across-study variation of true effects with a constant across-study variance τ^2 ; finally, the set of moderator variables, \mathbf{X} , includes:

- A dummy variable accounts for differences in methodology: FE_i is 1 if fixed effects were used to correct for unobserved workers' characteristics and 0 otherwise.

Two dummy variables reflect the gender composition of the sample: $FEMALE_i$ is 1 if estimates were obtained for female workers only and 0 otherwise, $-MALE_i$ 1 if estimates were obtained for male workers only and 0 otherwise. The reference categories for this set of dummy variables are estimates obtained with samples containing both female and male workers.

- Regional dummy variables are included to account for regional heterogeneity.
- $Self-employed_i$ is a dummy variable indicating that a study measured the wage gap between self-employed and formal employees.

²⁵ The random-effects meta-analysis estimate is a special case of a generalized method of moments estimator, where each estimate is weighted proportionally to its sampling error. Thus, it can only be applied to studies that reported standard errors of their inform-formal wage gap estimates.

ANNEX 4B Regression analysis

Correlation between informality, poverty, and income inequality. The following cross-country ordinary least squares regression model is estimated to show the association between informality and levels of extreme poverty and income inequality:

$$\bar{y}_i = \alpha_0 + \theta_1 \bar{x}_i + \theta_2 \overline{\text{LnGDPpc}_i} + \epsilon_i$$

The results are reported in table 4.6.

The dependent variable (\bar{y}_i) includes a range of measures for levels of poverty and income inequality averaged over 1990-2018 in country i . The level of poverty is proxied by the poverty headcount ratio at \$1.90 a day (2011 PPP) in percent of the total population. Measures for income inequality include the Gini coefficient (range from 0-100, with 0 being perfect equality and 100 being extreme inequality), survey mean consumption or income per capita of the lowest-income 40 percent of population, and the difference in consumption or income per capita levels between the bottom 40 percent of population and the total population (World Bank 2018). Lastly, the progress in shared prosperity, measured as the difference in the average annual growth in income or consumption of the poorest 40 percent of population and that of total population, is used as the dependent variable in column 6.

The variable of interest, \bar{x}_i , is the average level of informality in country i over the period 1990-2018, including the share of DGE/MIMIC-based estimates of informal output in official GDP, the share of self-employed in employed. All regressions control for income per capita, measured as the logged real GDP per capita in 2010 U.S. dollars averaged between 1990 and 2018 ($\overline{\text{LnGDPpc}_i}$). The proxies for poverty, income inequality, and shared prosperity are taken from World Development Indicators (WDI).

Declines in informality, poverty reduction and income equalization. The association between within-country changes in informality and poverty and inequality reduction is explored using a similar sample setup and methodology as in Dollar and Kraay (2002) and Dollar, Kleineberg, and Kraay (2013). In particular, the sample of country-year observations is assembled by starting with the first available observation for each country and selecting all available consecutive observations with at least a five-year distance between them (sampling window). This approach yields 428 country-year pairs for 32 advanced economies 119 EMDEs with at least 2 observation per country and a median of 4 observations per country. A median distance between observations is 5.5 years for EMDEs and 5 years for advanced economies. The sample excludes fragile and conflict states.

In table 4.7, the dependent variables are changes in poverty rates at US\$1.90 and US\$3.20 per day (in PPP terms) poverty lines at the end of the sampling window. In table 4.8, the dependent variables are changes in the Gini coefficient and shared prosperity at the end of the sampling window, where shared prosperity refers to the income share of the bottom 40 percent of the population.

The main variable of interest is the cumulative change of output (or employment) informality during the sampling windows. Employment informality is proxied by self-employment in percent of total employment, while output informality is measured by DGE-based estimates on informal output in percent of official GDP.

Additional control variables include initial poverty/inequality levels, which are measured at the start of the sampling windows, to capture persistence in poverty/inequality outcomes; initial levels of informality, cumulative GDP per capita growth during the sampling window; a constant; country and time fixed effects; and squared initial informality to control for the possible non-linear relationship between informality and poverty.

ANNEX 4C Bayesian Model Averaging approach

Model uncertainty is a common issue in regressions that investigate the correlates of informality. Past theoretical models and empirical studies have identified many potential drivers and implications of informality, ranging from social and economic factors underlying underdevelopment to institutional conditions (Schneider, Buehn, and Montenegro 2010; World Bank 2019). Bayesian Model Averaging (BMA) can address model uncertainty formally—by recognizing that the identity of the true model is unknown and that it may be preferable to combine evidence from many different models. Here the BMA model is used to show the potential correlates of output informality in EMDEs. A hyper-g prior is used for each coefficient, following Feldkircher and Zeugner (2012), which may achieve greater robustness than the priors used in the earlier literature. Priors on the inclusion probabilities are discussed below.

Grouping variables. Multiple variables can represent the same broad concepts. For example, both the share of population with primary schooling and above and the share of population with secondary schooling and above can proxy for the quality of human capital in that country. Bayesian approaches should be designed to take this into account (Durlauf, Kourtellos, and Tan 2008; Ghosh and Ghattas 2015). In the analysis underlying this chapter, variables that represent common concepts are grouped together following Dieppe (2020) and Durlauf, Kourtellos, and Tan (2008). As in their work, a group is deemed relevant if the posterior probability of including at least one variable from the group exceeds the prior inclusion probability. To account for the dependency within groups, the prior inclusion probability of each variable is defined as:

$$m_j^i = 1 - (1 - p_j)^{\frac{1}{k_j}}$$

where m_j^i , p_j , and k_j are the prior inclusion probability of variable i in the group j , the probability of including at least one variable from the group j , and the number of variables in group j , respectively. m_j^i is set so that the prior probability of including at least one variable out of the k_j variables in the group is equal to p_j . The quantity p_j is set

to 0.5 for all j , so there is no specific prior knowledge on the probability of a group's inclusion. Posterior distributions of the coefficients of the variables obtained from BMA are aggregated to the group level. The marginal impact of a group is defined as follows:

$$\beta_j^G = \sum_{\{i \in \text{Group } j\}} \beta_i PIP_i \delta_{j,i}$$

where β_j^G is the marginal impact of the group j , β_i is a posterior mean of variable given inclusion of the variable, PIP_i is a posterior inclusion probability of a variable, and $\delta_{j,i}$ is the factor loading of variable i in group j . A factor of group j is defined as the variable within a group whose coefficient posterior mean multiplied by the posterior inclusion probability is the highest. $\delta_{j,i}$ is the coefficient from the linear regression of a variable on the factor. β_j^G can be interpreted as the marginal impact of the factor, accounting for the correlations of the variables within groups. It can also be interpreted as the hypothetical posterior mean when including only one variable per group. In a linear regression, the factor-loading weighted sum of the coefficients is identical to the coefficient obtained by another regression (one that includes one variable per group).

Empirical specification. Following Loayza, Servén, and Sugawara (2010), analyses are carried out at the country level as the dependent variable. The explanatory variables ($\mathbf{X}_{j,t}$) are those identified as potential drivers or implications of informality by former theoretical or empirical studies.

Former studies show that the relationships between informality and its correlates in EMDEs may differ from those in advanced economies (Wu and Schneider 2019). To mitigate this issue, the analysis here includes only EMDEs. Based on data availability, the final sample covers an unbalanced panel for about 55 EMDEs over the period 1989-2018. Details about the list of group variables under investigation and their expected signs are summarized in table 4.9.

The level of output informality in country j in the beginning of a five-year period is modelled as follows:

$$y_{j,t} = \mathbf{X}_{j,t} \boldsymbol{\beta} + \theta_t + \varepsilon_{j,t}$$

where $y_{j,t}$ captures levels of informality at time period t in country j . Two measures of informality are used: informality as DGE-based informal output in percent of official GDP and share of self-employment. $\mathbf{X}_{j,t}$ is a vector of variables of interest, taking from the beginning year of period t and country j . θ_t controls for time fixed effects and $\varepsilon_{j,t}$ is a time varying unobserved idiosyncratic factor. To understand the cross-sectional variation of informality, as well as the time-series variation, country fixed effects are not included. The results are summarized in table 4.10 (output informality) and 4.11 (employment informality).

Limitations. The empirical strategy shown above tries to reduce country heterogeneity issues by restricting the sample to a relatively homogenous set. At the same time, it uses the BMA approach to overcome ad hoc variable selection and the arbitrary omission of

variables. However, the approach taken here cannot be used to draw any conclusions about causal effects. Since many explanatory variables (e.g., tax rates, government effectiveness, and financial development) could be viewed as equilibrium outcomes, which are jointly determined with informality, it is hard to draw conclusions about causal effects. Meanwhile, strong and valid instrumental variables that deal with this issue are hard to find. The analysis summarized here should be interpreted as correlates of informality levels. Another limitation of the model here is the omission of cyclical determinants, such as unemployment and macro-economic shocks. Due to the medium (to long)-run focus of the analysis here, cyclical factors that could be associated with short-run fluctuations in informality are not considered.

TABLE 4.1 Data: Meta regression analysis

Study	Countries/ estimates	Sample period	Methodology	Mean wage gap*

Source: World Bank.

Note: Productivity differential between the median informal and the median formal firm (last column) or between median informal firms among different groups of firms (all other columns). For example, "Manager has higher education" shows the difference in the median productivity among informal firms with managers with higher education and those without higher education. Other firm characteristics are not controlled for, hence results are similar but not identical to column (1) in table 4.4. Productivity is defined as annual sales (in 2009 U.S. dollars) relative to the number of workers. "All countries" is the unweighted average across each column. Significance is denoted by *** (1 percent), ** (5 percent), * (10 percent).

Note: Standard errors in parenthesis. Significance is denoted by *** (1 percent), ** (5 percent), * (10 percent). OLS regression with labor productivity as dependent variable, as proxied by annual sales (in 2009 U.S. dollars) per worker, based on a sample of formal firms only using World Bank's Enterprise Surveys data collected during 2007-14 for 4,036 informal firms and 7,558 formal firms in 18 countries. "Informal competition" is the share of firms in a cell (a group of firms of similar size in the same region and sector) that report competition from informal firms. It is worth mentioning that one could use a firm-level dummy rather than the proportion of formal firms in a cell to proxy informal competition. However, endogeneity concerns may arise because the informal competition faced by a specific firm may also be driven by its productivity. Therefore, the proportion of formal firms facing informal competition in a cell, which would be uncorrelated with the productivity of a specific firm, should be more robust to endogeneity concerns. "Manufacturing" is a dummy variable taking the value of 1 if a firm operates in the manufacturing sector and 0 otherwise. "Capital city" is a dummy variable taking the value of 1 if a firm is located in the capital city and 0 otherwise.

Source: World Bank.

Note: Robust standard errors in parentheses; *p<0.05, ** p<0.1. The sample of country-year observations starts with the first available observation for each country and all consecutive observations with at least five-year minimum window between them. Sample excludes fragile and conflict states. "Employment informality" is self-employment in percent of total employment. "Output informality" is proxied by DGE-based estimates on informal output in percent of official GDP. Dependent variables are changes in poverty rates at US\$1.90 and US\$3.20 per day. "GDP growth" denotes cumulative change in GDP per capita during the time window between observations. "Change in informality" denotes change in output (employment) informality during the time window between observations in percent of official GDP (in percent of official employment). "Lagged informality" denotes informality levels at t-1. Control variables include a constant, country and time fixed effects, and squared lagged informality to control for a possible non-linear relationship between informality and poverty. A positive coefficient on change in informality indicates that formalization reduces poverty.

Source: World Bank.

Note: Robust standard errors in parentheses; *p<0.05, ** p<0.1. "Shared prosperity" refers to the income share of the bottom 40 percent of population. The sample of country-year observations starts with the first available observation for each country and all consecutive observations with at least five-year minimum window between them. Sample excludes fragile and conflict states. "Employment informality" is self-employment in percent of total employment and "output informality" is proxied by DGE-based estimates on informal output in percent of official GDP. Dependent variables are two measures of inequality: the change in Gini coefficient and shared prosperity. "GDP growth" denotes cumulative change in GDP per capita during the time window between observations. "Change in informality" denotes change in output (employment) informality during the time window between observations in percent of official GDP (in percent of official employment). "Lagged informality" denotes informality levels at t-1. Control variables include a constant, country and time fixed effects, and squared lagged informality to control for a possible non-linear relationship between informality and inequality. A positive coefficient on change in informality indicates that formalization reduces shared prosperity (the income share of the bottom 40 percent of population).

TABLE 4.9 Data: Bayesian Model averaging approach

Group	Expected sign (group)	Variable	Source
Economic development	(-)	Share of population in urban area	WDI
		Labor productivity (in logs)	WDI
		Share of manufacturing (in percent of value added)	WDI
		Share of manufacturing (in percent of employment)	WDI
Human capital	(-)	Human capital	UNDP
		Share of population with primary schooling and above	Wittgenstein Center for Demography and Global Human Capital
		Share of population with secondary schooling and above	
Financial development	(-)	Domestic credit to private sector (in percent of GDP)	WDI
Trade openness	(-/+)	GVC position index	UNCTAD
		GVC participation index	UNCTAD
Governance	(-)	Political rights index	Freedom house
		Civil rights index	Freedom house
		Accountability	WGI
		Regulatory Quality	WGI
		Control of Corruption	WGI
		Political stability	WGI
Tax burdens	(+)	Government expenditure (in percent of GDP)	WDI
		Tax revenues (in percent of GDP)	IMF GFS
		Electricity consumption per capita	WDI
Access to public infrastructure	(-)	Access to Basic Water, rural/Urban	WDI
		Air goods transported	WDI
		Road length per capita	World Road Statistics

Source: World Bank

Note: The expected signs are for each group of variables. They summarize the relationship between each group of variables and the level of informality suggested by past studies. “(-)” (“+”) suggests that an increase in the corresponding group variable would be associated with a fall (increase) in output informality. Among all groups, only the group of variables on tax burdens are expected to be positively associated with output informality, suggesting that higher tax burdens are associated with a higher level of informal output. In the case of trade openness, its relationship with informality could be either positive or negative, as suggested by former studies (chapter 6).

Law and order	2.9	3.6	0.00	2.9	3.8	0.00

Sources: Barro and Lee (2013); *International Country Risk Guide (ICRG)*; World Bank (*Doing Business*, World Development Indicators).

Note: Data are from emerging market and development economies (EMDEs) and the period 1990-2018. "High" are EMDEs with above median Multiple Indicators and Multiple Causes model (MIMIC)-based informal output measures (perceived informality measured by the World Economic Forum's index, reversed order), while "Low" are EMDEs with below median MIMIC-based informal output measures (perceived informality). "P-val" shows the p-values of the t-tests conducted for the group comparisons. The correlates include GDP per capita (in logs; 2010 U.S. dollars); access to credit (domestic credit to private sector in percent of GDP); human capital (average years of schooling); trade openness (the sum of imports and exports in percent of GDP); the ease of doing business score (the score is reflected on a scale from 0 to 100, where 0 represents the lowest and 100 represents the best performance); bureaucracy quality; control of corruption; and law and order (ICRG). Higher values corresponding to better outcomes.

Source: World Bank.

Note: See the notes to figures 4.1-4.8 for detailed definitions and data sources for various dependent variables. Development outcomes are regressed against a set of dummies that categorize emerging market and developing economies (EMDEs) into quantiles of shares of informality using dynamic general equilibrium (DGE)-based estimates on informal output in percent of official GDP. The constant from the regression results show the development outcomes for the lowest quartile; coefficients show the difference between the corresponding quartile and the lowest quartile. All regressions are cross-sectional, with variables averaged during (up to) 1990-2018 (or otherwise specified period or latest year available). Robust standard errors in parentheses. *** p<0.01, ** p<0.05, * p<0.1

Source: World Bank.

Note: See the notes to figures 4.1-4.8 for detailed definitions and data sources for various dependent variables. Development outcomes are regressed against a set of dummies that categorize emerging market and developing economies into quantiles of shares of informality using self-employment in percent of total employment. The constant from the regression results show the development outcomes for the lowest quartile and coefficients show the difference between the corresponding quartile and the lowest quartile. All regressions are cross-sectional regressions with variables averaged during (up to) 1990-2018 (or otherwise specified period or latest year available). Robust standard errors in parentheses. *** p<0.01, ** p<0.05, * p<0.1

CHAPTER 5

Informality in Emerging Market and Developing Economies: Regional Dimensions

Emerging market and developing economies (EMDEs) experienced a decline in informality over the two decades prior to the COVID-19 pandemic. Output informality declined most in East Asia and Pacific (EAP) and South Asia (SAR), while employment informality fell most in the Middle East and North Africa (MNA), SAR, and Sub-Saharan Africa (SSA). Yet the incidence of informality remains high in all regions. In SAR and SSA, pervasive informality has been associated with low human capital and large agricultural sectors. In Europe and Central Asia (ECA), Latin America and the Caribbean (LAC), and MNA, heavy regulatory and tax burdens and weak institutions have been important factors. Also important have been legacies of the transition from central planning to market economies in ECA and disruptions related to conflict in MNA and SSA. In EAP, employment informality is associated with lagging social protection in cities following large-scale rural-to-urban migration. A balanced policy mix tailored to economy-specific circumstances can help mitigate the adverse effects of informality.

Introduction

Informal economic activity is pervasive in emerging market and developing economies (EMDEs), accounting for one-third of GDP, on average. Self-employment, a commonly used proxy for informal employment, averages about two-fifths of total employment. For various reasons, including flexibility, some firms and workers choose to remain informal. In some cases, informal work may be the only option. High levels of informality are associated with low labor productivity and low tax revenues, and can further entrench poverty and inequality.

Informality fell in the average EMDE in the two decades before the COVID-19 pandemic, although the pace of decline varied across regions and countries. The correlates of informality also vary across regions, shaped by distinctive regional cultures and histories, as well as economic, social and policy structures.

This chapter addresses the following questions:

- How has informality evolved over the past two decades in each EMDE region?
- What are the correlates of informality in each region?

Note: This chapter was prepared by Dana Vorisek, Gene Kindberg-Hanlon, Wee Chian Koh, Yoki Okawa, Temel Taskin, Ekaterine Vashakmadze, and Sandy Lei Ye. Research assistance was provided by Hrisyana Doytchinova and Arika Kayastha.

- What policy options are available to address the challenges associated with informality in each region?

Several techniques have been developed to measure informality (chapter 2).¹ For the analysis here, output informality is proxied by dynamic general equilibrium (DGE) model-based estimates, in percent of official GDP, and employment informality refers to the share of self-employment in total employment, unless otherwise indicated. These measures are chosen because of their extensive economy and time-series coverage.

Contributions. The chapter makes several contributions to the literature. First, the chapter brings a regional perspective to the existing literature on informality in EMDEs. Past studies either grouped all economies together or focused on one or a few economies or a specific region. The chapter distills commonalities among EMDEs within each region and differences across regions. Second, the chapter brings together multiple strands of literature by investigating two key types of informality—output and employment informality—thus helping policy makers better understand the nature of informality in their respective regions (chapter 4). Previous studies typically examined either output informality or employment informality. Lastly, the chapter provides policy recommendations that are tailored to region-specific needs and conditions. Former studies tend to have a broad overview of all relevant policies without applying them to the regional context.

Main findings. First, the chapter documents large differences in the evolution of informality across regions. Output informality is highest in ECA, LAC, and SSA, while employment informality is highest in EAP, SAR, and SSA. Output informality declined most in EAP and SAR between 1990-99 and 2010-18, while employment informality fell most in MNA, SAR, and SSA. Despite declines in output informality, and consistent with slower productivity growth in the informal than the formal sector, employment informality remained broadly unchanged in EAP, ECA, and LAC between 1990-99 and 2010-18.

Second, a mix of cross-regional, intra-regional, and economy-specific factors are associated with informality in EMDEs. Key correlates of high informality include low human capital, large agricultural sectors, and poor business climates. But there are also important region-specific factors, such as insufficient social protection coverage, trade liberalization, and economic disruptions due to armed conflict. Reflecting regional as well as national differences in informality, balanced policy mixes tailored to economy circumstances are required to set the right conditions for informality to fall.

¹Three methods of estimating informal output are used in this book. The DGE method refers to the dynamic general equilibrium (DGE) model of Elgin and Oztunali (2014). It estimates the allocation of labor between the formal and informal sectors based on the assumption of utility maximization by an infinitely lived representative household endowed with certain units of productive capital and time. An alternative, multiple indicators multiple causes (MIMIC) method is based on a model comprising structural equations that use observable causes and indicators to capture the latent level of informal output. A third method of uses survey data on perceptions of informal activity obtained by the World Economic Forum, World Values Survey, and World Bank Enterprise Surveys. Chapter 2 contains a detailed discussion of these and other measures of informality and their limitations.

The remainder of the chapter is structured as follows. The next section provides an overview of informality in EMDEs. The subsequent sections discuss the evolution of informality in each of the six EMDE regions. Each of these sections examines the correlates of informality and presents region-specific policy options to address the challenges associated with informality. The last section concludes with a discussion of emerging opportunities and policy challenges.

Informality in EMDEs

Informality is far more widespread in EMDEs than in advanced economies (figure 5.1). Informal output in EMDEs was, on average, 33 percent of official GDP between 2010 and 2018, while self-employment accounted for 42 percent of total employment. These shares were 18 and 14 percent, respectively, in advanced economies. Of the six EMDE regions, output informality is highest in ECA, LAC, and SSA. Employment informality is highest in EAP, SAR, and SSA.

Informality has declined in both advanced economies and EMDEs over the past two decades, but by more in EMDEs (figure 5.1; chapter 2). In EMDEs, output informality decreased by 8 percentage points between 1990 and 2018, while employment informality fell by about 9 percentage points, with increases in the mid-1990s and early 2000s subsequently reversed.

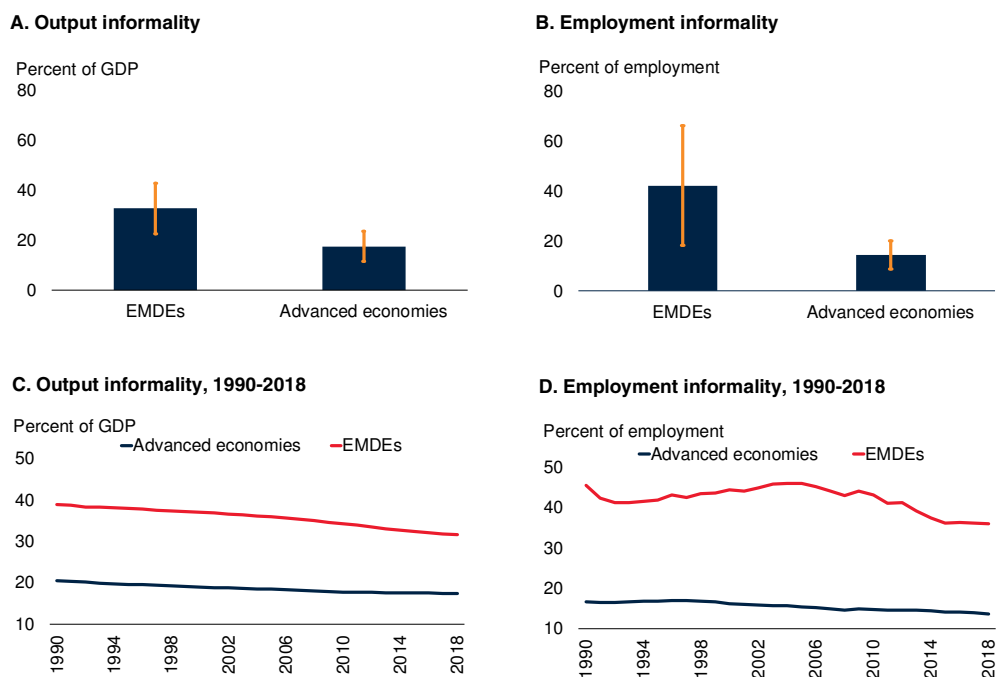

EMDEs account for half of the world's informal output and more than 90 percent of its informal employment (figure 5.2). Three EMDE regions—EAP, LAC, and ECA—account for more than one-third of the world's informal output. These are also the largest EMDE regions in terms of official GDP. EAP and SAR account for the largest shares, by far, of informal employment at the global level. These two regions' shares of global informal employment are three times and eight times as large, respectively, as their shares of global informal output, implying that productivity is particularly low among informal workers in EAP and SAR.

EAP and SAR also experienced the largest declines in output informality between 1990-99 and 2010-18, in large part reflecting rapid economic development in China and India. The sharpest decline in employment informality occurred in SAR, followed by MNA and SSA. Despite declines in output informality, employment informality increased slightly in EAP and LAC. This may reflect, in part, rigid labor markets and burdensome regulations (LAC) and mismatch between rapidly expanding jobs during urbanization and lagging social protection coverage as demographic conditions changed (EAP). Informality—especially employment informality—is most prevalent in EMDEs with low income per capita, reflecting the role of informality as both a driver and a consequence of poverty (figure 5.2; La Porta and Shleifer 2014).

Informality in EMDEs is associated with numerous factors, well documented in the literature. EMDEs with the highest incidence of informality tend to have weak human capital (less educated and less skilled workers), large agricultural sectors, and poor

FIGURE 5.1 Evolution of informality in advanced economies and EMDEs

Informality is far more widespread in emerging market and developing economies (EMDEs) than in advanced economies. Output and employment informality have declined in both groups, but by more in EMDEs.

C.D. Lines show unweighted group averages for each year.

institutional environments (for instance, high corruption or restrictive regulations; figure 5.3; chapter 4). In SAR, and SSA, for instance, agricultural production still makes up a large share of employment in many economies.

Other key correlates of informality differ among regions. In EAP, large-scale rural-to-urban migration in recent decades supported rapid growth and industrialization. Although this migration has been accompanied by falling output informality, employment informality increased, because of lagging social protection. In ECA, the high shares of informal output in some economies are partly a legacy of the transition from centrally planned to market economies. In LAC, trade liberalization reforms of the 1990s contributed to growing informality in some economies, as formal firms that were unable to compete in a liberalized formal economy retreated into informality. In MNA and SSA, economic disruptions during armed conflicts have forced people to earn their livelihoods in the informal economy.

FIGURE 5.2 Informality in EMDE regions

Employment informality tends to be higher than output informality in EMDE regions. Low per capita income is associated with high informality, especially employment informality.

The COVID-19 pandemic has hit the informal sector hard. An estimated three-quarters of the world's informal workers were significantly impacted by lockdowns in early 2020 (ILO 2020). In many economies, informal firms are concentrated in the services sector, which has been subject to more disruption from government-imposed mobility restrictions than the industrial or agricultural sectors due to reliance on face-to-face interactions. However, because informal workers are often not registered in government systems, many have been out of reach of social assistance programs. If unreachable through benefits programs, informal workers are likely to feel compelled to continue working, despite the health risks (Maloney and Taskin 2020). Encouragingly, the policy response to COVID-19 in some EMDEs has included the provision of benefits to informal workers, including through digital platforms, although the adequacy and coverage of benefits to informal workers was far from complete (Dabla-Norris and Rhee 2020; Díez et al. 2020; Frost, Gambacorta, and Shin 2021).

East Asia and Pacific

The EAP region experienced a sharp decline in output informality over the past two decades. This decline was broad-based within the region. However, there remain pockets of high informality, in particular in several lower-middle-income economies characterized by large rural sectors, poor governance, weak institutions, and low human capital (Cambodia, Lao People's Democratic Republic, and Myanmar).

Although many economies in the region have made considerable progress in integrating rural migrants into urban labor markets, they still face challenges related to urban informality. EAP has large slum populations. Many urban dwellers are informal workers with inadequate social protection and without access to basic services like clean water and public transportation. While cities across East Asia have propelled the region's rapid economic growth, there remain challenges in expanding opportunities, including to unregistered migrants living in urban peripheries. Reforms to urban planning can help expand access to opportunities.

The COVID-19 pandemic is taking a severe toll on micro, small, and medium-sized enterprises (SMEs), which are the sources of livelihood for most informal workers. The pandemic and resulting lockdowns, given the limited access in the informal sector to social support and digital technologies, are likely to have increased inequality. Policies that focus on skills upgrading and improving access to resources, such as business development services, can help reverse this.

Evolution of informality in EAP

Informal output in EAP was equivalent to 27 percent of official GDP, on average, in 2010-18, below the EMDE average and down from 35 percent of GDP in 1990-99 (figure 5.4). Survey-based measures of informality in EAP, such as perceptions of informal activity, also indicate a decline. However, informal employment (as measured by self-employment), at 50 percent of total employment, was higher than the EMDE average in 2010-18 and has increased slightly over the past two decades. In an alternative measure of employment informality, the share of labor without basic pension coverage, approximately 75 percent of EAP employment can be categorized as informal in recent years.

Declining output informality in EAP has been accompanied by sustained economic growth, rapid industrialization and urbanization, and improvements in institutional quality (Loayza 2016; World Bank 2015). Between 1990-99 and 2010-18, the share of informal output declined rapidly in the fastest-growing economies, in part reflecting the effects of comprehensive reforms. For example, the share of informal output in GDP in Myanmar fell by 33 percentage points, to below 30 percent in 2010-18, following broad-based liberalization measures (figure 5.4).

FIGURE 5.4 Informality in East Asia and Pacific (EAP)

Compared with other EMDE regions, EAP's share of informal output is moderate, whereas its share of informal employment is above average. Informality is particularly high in lower-income economies, which are also characterized by more stringent labor regulations and lack of enforcement.

A. Output informality

B. Employment informality and perceptions of informality

C. Output informality in selected economies

D. Range between employment and output informality

Sources: International Labour Organization; World Bank; World Economic Forum (2018).

Note: EAP = East Asia and Pacific; EMDE = emerging market and developing economies.

A,B. Blue bars show unweighted averages of the informal economy of the region. Red markers show unweighted averages of all EMDEs and the vertical lines denote the interquartile range of all EMDEs.

A. DGE = dynamic general equilibrium model; MIMIC = multiple indicator multiple causes model. Both models estimate the size of the informal sector as a percent of official GDP. DGE sample includes 12 EAP economies and 122 EMDEs; MIMIC sample includes 14 EAP economies and 124 EMDEs.

B. Self-employment is measured as percent of total employment. The World Economic Forum (WEF) asks the following question: "In your country, how much economic activity do you estimate to be undeclared or unregistered? (1 = Most economic activity is undeclared or unregistered; 7 = Most economic activity is declared or registered)." The average responses are used to capture the extent of perceived informality. The index is reversed here so that a lower WEF index indicates a larger informal economy. Self-employment sample includes 19 EAP economies and 134 EMDEs; WEF sample includes 19 EAP economies and 134 EMDEs.

C. Output informality is based on DGE estimates, in percent of official GDP.

D. The upper bound of each bar indicates the latest available share of self-employment in total employment. The lower bound indicates the latest available share of informal output in official GDP, based on DGE estimates. For Malaysia, not shown, the level of informal output is slightly higher than the level of informal employment. Data for last available year.

Employment informality in upper-middle-income economies is about two-fifths lower than in lower-middle-income economies. In a pattern consistent with per capita incomes, output informality is also lower, by about one-tenth.²

²Although the commonly observed link between per capita income and informality generally holds in the EAP region, there are outliers. Thus, informality is relatively high in Thailand despite its higher-middle-income status.

In lower-middle-income economies, the share of informal employment far exceeds the share of informal output, reflecting low labor productivity in the informal sector. The differentials are particularly pronounced in Indonesia, Lao PDR, Mongolia, and Vietnam (figure 5.4).

Correlates of informality in EAP

The extent of informality in EAP is associated with several economic and institutional factors, particularly the size of the agricultural sector and human capital development, as well as firm structure, regulatory burdens and the quality of governance. Informality is also correlated with such socio-economic variables as poverty and inequality, which may exacerbate the vulnerability to shocks of households in the informal sector (chapter 4).

Urbanization. EAP is the world's most rapidly urbanizing region: the urban population grew by an average of 3 percent annually during 1978-2015 (Judy and Gadgil 2017). Rapid industrialization in EAP has supported large-scale rural-to-urban migration and stimulated growth of output, labor productivity, and employment (Ghani and Kanbur 2013). Urbanization has coincided with a shift from agriculture to manufacturing and services in China and other fast-growing East Asian economies (McMillan, Rodrik, and Sepúlveda 2017; Rodrik 2015). In general, larger non-agricultural sectors are associated with lower informal output, and informality in manufacturing is significantly lower than in services (figure 5.5; Atesagaoglu, Bayram, and Elgin 2017). In economies such as Myanmar, Indonesia, and Lao PDR, informal employment accounts for about 80 percent of total non-agricultural employment (World Bank 2020a).

However, rapid growth of cities in EAP has been accompanied by rising urban informality and policy challenges, such as lack of affordable housing, growing slums, poor provision of basic services, and widening income inequality among urban dwellers. In China, for example, there is unequal access to public services between citizens with urban household registration under the *hukou* system and those without, with many unregistered urban households still lacking essential social protection (Park, Wu, and Du 2012; World Bank 2014). Despite having the lowest employment and output informality in EAP, China is estimated to have approximately 120-150 million rural-to-urban migrants who are not registered to work in cities (Gagnon, Xenogiani, and Xing 2011; Huang 2009; Jutting and Xenogiani 2007). Much of the urban slum population is informally employed, with significantly lower wages than in the formal sector (Judy and Gadgil 2017). The cities with the largest numbers of urban poor are in China, Indonesia, and the Philippines, while the highest urban poverty rates are in the Pacific Island countries of Papua New Guinea, Timor-Leste, Vanuatu, as well as in Indonesia and Lao PDR.

Firm structure. Economic reforms in China and Vietnam that began in the 1970s have allowed the emergence of private sector activity in the form of unregulated micro-enterprises, family enterprises, and individual entrepreneurs (Park, Wu, and Du 2012). The informal economy in these and other economies mostly comprises such enterprises. For example, in Indonesia, most informal firms have fewer than five employees. These

FIGURE 5.5 Correlates of informality in East Asia and Pacific (EAP)

Better institutions and business environments, industrialization, and urbanization are associated with relatively low informality in higher-income economies. Economies with higher shares of informality have lower levels of educational attainment.

A. Agricultural employment and self-employment are share of employment in agriculture and share of self-employed in total employment, respectively. Data for 2018.

C. The Human Capital Index (HCI) calculates the contributions of health and education to worker productivity. The final index ranges from zero to one and measures the productivity as a future worker of a child born today relative to the benchmark of full health and complete education. The vertical and horizontal lines denote EMDE averages. Data for the latest year available.

D. Total years of schooling is the average years of education completed by people over age 15. Data for the latest year available.

E. A higher value indicates better institutional quality. Error bars reflect values from all EMDEs in EAP. "High informal employment" includes EAP EMDEs with above-median informality over the period 2010-18; "low informal employment" includes those with below-median informality over the same period. Data for the latest year available.

F. "Higher MICs" include China, Malaysia, and Thailand. "Middle MICs" include Indonesia, Mongolia, and the Philippines. "Lower MICs" include Cambodia, Lao PDR, Myanmar, and Vietnam. These groupings are based on GDP per capita.

firms also tend to be less productive than larger firms, and they pay lower wages. Their operations predominantly supply local markets and they have little ambition for expansion (Rothenberg et al. 2016).

Policy options to address informality challenges in EAP

A distinctive feature of EAP is its large number of slum dwellers. Informality tends to be high among these populations. Targeted policies to improve urban planning can improve living conditions and provide more equal opportunities to informal workers in these settlements. In lower-middle-income economies, underinvestment in human capital and persistently low labor productivity warrant attention. In addition, complementary broad-based measures, such as improving governance and removing disincentives to formal employment, could be pursued.

The COVID-19 pandemic has exposed the challenges in protecting informal workers and vulnerable households in Asia. But it has also provided an opportunity to address longstanding inequalities—in access to health and basic services, finance, and the digital economy—and to enhance social protection for informal workers (Dabla-Norris and Rhee 2020).

Urban planning reforms. Agglomeration benefits can lower the unit costs of public service provision in cities, enabling governments to extend access to basic services to more people (Ghani and Kanbur 2013). To leverage these benefits, urban plans must be well-designed to help improve access to jobs, affordable housing, commercial services, public transportation, and health and education services, thus providing more equal opportunities to disadvantaged communities (Judy and Gadgil 2017; World Bank 2015). Examples of effective metropolitan governance include Beijing, Jakarta, Kuala Lumpur, Metro Manila, and Shanghai (World Bank 2015; World Bank and DRCS 2014).

Increasing labor productivity. A shift into the formal sector does not necessarily increase labor productivity in firms (Demenet, Razafindrakoto, and Roubaud 2016). Supporting policies need to be in place, including to improve access to business development services, decrease red tape and corruption, facilitate access to financial services, and offer better education and training (OECD 2009; World Bank 2019a). These policies are especially important for small agricultural enterprises, which engage a large share of EAP's workforce.

Reducing regulatory burdens. Removing disincentives to formal employment could encourage a shift of informal firms into the formal sector. Policies can include less burdensome registration procedures and costs and simpler tax assessment and payment regimes. Such broad-based reforms to improve the business climate are also important for formal firms, incentivizing them to invest, grow and create more jobs. These measures could be complemented with strengthening enforcement to increase the benefits of regulatory compliance.

Widening social protection coverage. Investment in social-support systems can be scaled up, systems can be more effectively targeted and, where possible, linked with existing education, health and employment support mechanisms. The tax base can be widened, the progressivity in taxation increased, and financing of social insurance schemes can be expanded (OECD 2019). The pandemic provides an important opportunity for policy makers to take measures to strengthen social protection systems, including ability to adapt to future shocks (World Bank 2020a).

Europe and Central Asia

The incidence of informality in ECA differs markedly between the eastern and western portions of the region. The east, with weaker institutions and less conducive business climates, has significantly higher informality than the western part (figure 5.6). Higher informality in the east can also be attributed partly to larger agricultural sectors and to sizable remittance inflows which have provided capital to establish small, informal businesses.

Some ECA economies have had success with policies to promote lower informality, including reductions in tax compliance burdens and tax rates. Policies to promote more flexible labor markets have also been associated with reductions in informal employment. For economies in the east, building stronger institutions, strengthening enforcement, and controlling corruption can encourage businesses to operate in the formal economy.

Evolution of informality in ECA

With the collapse of central planning in ECA in the late 1980s, the informal sector expanded dramatically. Many firms chose to operate informally to avoid regulations, taxation, or corruption, but also because informal activities were profitable due to rationing of consumer goods and high inflation (Johnson, Kaufmann, and Shleifer 1997). During 1989-95, the size of the informal economy more than doubled. Since then, informality in ECA has fallen slightly, from an average of 39 percent of official GDP in 1990-99 to 36 percent in 2010-18; it is still slightly higher than the EMDE average (figure 5.6). Survey-based measures of informality in ECA, such as perceptions of informal activity, also indicate a downward trend. Employment informality (measured by self-employment), however, was unchanged between 1990-99 and 2010-18, at 30 percent of total employment.

Since the 1990s, the western portion of ECA has experienced a faster decline in informality than the east, reflecting more progress with market liberalization and other reforms and less corruption than in the east (Kaufmann and Kaliberda 1996). Notwithstanding the larger decline in informality in the west of the region, one in ten formal employees in Central Europe still received “envelope wages” as recently as 2006.³

³ “Envelope wages” refers to the practice of paying a portion of wages in undeclared cash to avoid tax and social security contributions (Williams and Padmore 2013).

FIGURE 5.6 Informality in Europe and Central Asia (ECA)

Output informality in ECA has been higher than the EMDE median since the 1990s, and has declined at roughly the same pace as in other regions. But employment informality in ECA has been lower than the EMDE average. Within ECA, informality has been higher and has declined more gradually in the east.

"West" includes Central Europe (Bulgaria, Croatia, Hungary, Poland, and Romania), the Western Balkans (Albania, Bosnia and Herzegovina, Kosovo, Macedonia, Montenegro, and Serbia), and Turkey.

C. Data are for the latest year available, in most cases, for 2018. Orange diamonds indicate subsample averages and blue bars indicate the one-standard deviation range. Output informality is based on DGE estimates, in percent of official GDP.

Correlates of informality in ECA

Informality in ECA has been associated with several economic and institutional factors, including the size of the agriculture sector, remittances, and institutional quality. Informality has also had socio-economic consequences, such as greater income inequality

arising from lower wages in the informal sector and lower fiscal revenues and capacity, as informal firms do not pay taxes.

Remittances. Several economies in ECA (in particular, the Kyrgyz Republic and Tajikistan) are among the most remittance-reliant in the world in terms of inflows as a share of GDP (World Bank 2020b). At the household level, high levels of remittances inflows are associated with a higher likelihood of working informally in ECA (Ivlevs 2016). Remittances can provide capital to help establish small businesses, which tend to be informal, and income support that can make it easier to engage in less secure but often more lucrative informal work (Chatterjee and Turnovsky 2018; Shapiro and Mandelman 2016).

Institutions. Institutional quality is better in ECA, on average, than in the average EMDE, but it varies widely, with much weaker indicators in the eastern part of the region (figure 5.7). The west has seen marked improvements in its institutional environment, including more effective government, better regulatory quality, strengthened enforcement, and less corruption, in part owing to reforms implemented in the context of the European Union (EU) accession process (Kaufmann and Kaliberda 1996). These gains have contributed to substantial improvements in the business environment, encouraging firms to operate in the formal sector.⁴

Wage gaps. Traditionally, workers are thought to seek informal work when formal employment opportunities are scarce and when they are less productive (box 4.1). But the informal sector can also provide opportunities to develop human capital helpful for eventual formal employment or self-employment, as has been found for the Russian Federation and Turkey (Guariglia and Kim 2006; Taymaz 2009). In some ECA economies (Russia, Romania, Tajikistan, and Ukraine), informal workers have been found to earn a wage *premium* over formal workers, which may compensate for the lack of social security and lower job security.⁵ Relatively high wages in the informal sector may encourage skilled professionals to forgo emigration opportunities in highly regulated economies experiencing high rates of emigration, such as Tajikistan (Abdulloev, Gang, and Landon-Lane 2011).

Fiscal revenues. Within ECA, large informal sectors are associated with lower tax revenues and lower provision of public goods (figure 5.7). However, the magnitude of revenues lost because of informality is a matter of debate. One estimate is that tax revenue losses from informality could have been as high as 7 percent of GDP in Armenia in 2004 (Grigorian and Davoodi 2007). Survey data, however, point to only modest potential revenue gains (0.03-0.07 percent of GDP) from turning informal workers into formal workers in Ukraine in 2009, as the newly formal sector workers would typically be low-skilled and subject to low tax rates (World Bank 2011).

⁴ However, the transition from economies dominated by large-state owned enterprises to more private-business friendly economies can sometimes create more informal employment and a larger informal sector (Earle and Sakova 2000).

⁵ See, for instance, Lehmann and Norberto 2018, Shehu and Nilsson 2014, Staneva and Arabsheibani 2014, and Zahariev 2003.

FIGURE 5.7 Correlates of informality in Europe and Central Asia (ECA)

As in other regions, employment informality in ECA tends to be higher in countries with larger agricultural sectors. Output informality is higher in the eastern part than in the western part of the region, in part reflecting differences in institutional quality.

Note: ECA = Europe and Central Asia; EMDE = emerging market and developing economies.

A. Agricultural employment and self-employment are share of employment in agriculture and share of self-employed in total employment, respectively. Data for 2018. Sample includes 21 ECA countries.

B.C. Data for 2016 in most cases. "East" includes Armenia, Azerbaijan, Belarus, Georgia, Kazakhstan, Kyrgyz Republic, Moldova, Russia, Tajikistan, Ukraine, and Uzbekistan. "West" includes Albania, Bosnia and Herzegovina, Bulgaria, Croatia, Hungary, Kosovo, Montenegro, North Macedonia, Poland, Romania, Serbia, and Turkey.

D. Values are latest available five-year averages for tax revenue, total revenue and social benefit expenditure from the general government including social security system. High/low informality are median of top/bottom 50 percent of output informality in ECA sample of economies, as measured by average dynamic general equilibrium (DGE) estimates during 2010-18.

Policy options to address informality challenges in ECA

Policies that are effective in other EMDE regions or even in a particular economy within ECA could be counter-productive for another economy in the region. This underscores the importance of tailoring reforms to economy-specific circumstances. In ECA, policies to tackle informality have centered around fiscal policies, reforms of institutional environments, and labor market policies.

Fiscal reforms. Within ECA, large informal sectors are associated with lower tax revenues and lower provision of public goods, which is a general pattern in EMDEs (figure 5.7; chapter 4). However, the magnitude of revenues lost because of informality

depends on economy circumstances. Typically, reducing the tax compliance burden and tax rates, as well as subsidizing the transition to formality, has been accompanied by declines in informality.⁶

- *Preferential tax schemes.* One form of tax simplification that has been used in ECA is the introduction of presumptive taxation for the self-employed and small firms (IFC 2007). This can encourage entrepreneurship, increase revenue collection from hard-to-tax sectors, and ease the transition from informal to formal work. However, these schemes may also inadvertently encourage formal workers to avoid taxes by shifting into presumptive tax status, and encourage firms to remain small (Packard, Koettl, and Montenegro 2012).
- *Other taxes.* Shifting from labor income taxes, which constitute a wedge between informal and formal employment, to less distorting and more easily enforced taxes, such as value-added taxes and progressive real estate or land taxes, can shrink the informal economy (Packard, Koettl, and Montenegro 2012). Such shifts occurred in several ECA economies, such as Azerbaijan and Georgia, after 2000 (Végh and Vuletin 2015).
- *Subsidies.* A formal employment subsidy introduced in Turkey in 2004 and 2005 led to an increase in the number of registered jobs by encouraging informal workers to transition to formal employment, including through better social protection (Betcherman, Daysal, and Pagés 2010).

Building institutions. Better governance and more effective tax collection authorities can reduce the size of the informal economy and increase tax revenue. Corruption has been associated with greater informal activity in Poland and Romania (Johnson et al. 2000). Conversely, better control of corruption has reduced the extent of informal activities, particularly in countries that joined the EU in the mid-2000s (Fialová and Schneider 2011). The eastern part of the region, which has much weaker institutions, could focus on improving governance, strengthening enforcement, and fighting corruption, to mimic the favorable outcomes observed in the west.

Labor market regulations. More restrictive employment protection legislation has been associated with higher informal output and employment in ECA, supporting the case for increasing labor market flexibility (Fialová and Schneider 2011; Lehmann and Muravyev 2009). This can take the form of less restrictive regulations with respect to hiring and dismissal, working arrangements, and wage levels.

COVID-19. With informal and formal workers both having lost wages during the COVID-19 pandemic, new wage support programs have targeted both types of workers.

⁶On one hand, higher labor tax rates encourage a movement into untaxed informal employment, especially for low-wage earners (Koettl and Weber 2012). On the other hand, higher labor tax rates have in some cases been associated with a lower share of informal employment, because higher revenue allow governments to provide better public goods that can only be accessed in formal employment (Fialová and Schneider 2011; Friedman et al. 2000).

Success in reaching the informal sector has been uneven across economies, however. Support programs in ECA, including cash transfers, have also covered informal workers and firms, albeit to a smaller degree than formal workers (World Bank 2020c). Meanwhile, in Central Asia, large informal sectors and low digitalization in Central Asia may have slowed the transition to online sales that has helped other countries weather the pandemic (EBRD 2020).

Latin America and the Caribbean

A confluence of factors—labor market inefficiencies, burdensome regulations and taxation, corruption, and vast economic and social inequalities—create an environment that has allowed informality to flourish in LAC. Although output informality in LAC has steadily declined over the past two decades, it remains slightly higher than the EMDE median. The trend in employment informality has been less clear. The COVID-19 pandemic has brought new challenges: providing income support to informal workers, many of whom were already living hand-to-mouth before the pandemic and have faced severe income losses during it, became an urgent priority.

Although the quality of institutions in LAC is on average stronger than in EMDEs as a whole, countries in the region with low institutional quality indicators have higher informality. Informality has increased in countries with rampant corruption. High tax rates or burdensome tax regulations may also have encouraged firms to stay in the informal sector. Informality in LAC has been associated with weak growth of output and labor productivity, as well as worse poverty and inequality outcomes. Redesigning tax policy, increasing enforcement of labor laws, and improving the business climate have had some success in reducing informality in the region.

Evolution of informality in LAC

Output informality in LAC has fallen over the past two decades. On average, informal output was equivalent to 35 percent of official GDP in 2010-18, marginally higher than the EMDE average, down from 40 percent in 1990-99 (figure 5.8). A survey-based measure of perceptions of informal activity has also fallen. However, informal employment (measured by self-employment) as a share of total employment increased by about 2 percentage points from 1990-99 to 2010-18, to 36 percent, which was still below the EMDE average. The COVID-19 pandemic is likely to have sharply increased the informal share of employment, at least temporarily, and at the same time, informal workers have suffered disproportionately large income losses.

The decline in output informality over the past two decades has been broad-based across the region (figure 5.8). Several of the countries with the highest incidence of output informality, such as Bolivia, Panama, and Peru, experienced some of the largest declines over the past two decades, in part due to rapid formal job creation in the context of strong output growth. In most countries, employment informality is higher than output informality, reflecting lower productivity in the informal than the formal sector.

FIGURE 5.8 Informality in Latin America and the Caribbean (LAC)

Output-based informality in LAC has fallen since the 1990s, on average, but remains above the EMDE median. Employment-based informality has been stable in the region as a whole; it has increased in several countries.

A. DGE = dynamic general equilibrium model; MIMIC = multiple indicator multiple causes model. Both models estimate the size of the informal sector as a percent of official GDP. DGE sample includes 26 LAC economies and 122 EMDEs; MIMIC sample includes 25 LAC economies and 124 EMDEs.

B. Self-employment is measured as percent of total employment. The World Economic Forum (WEF) asks the following question: "In your country, how much economic activity do you estimate to be undeclared or unregistered? (1 = Most economic activity is undeclared or unregistered; 7 = Most economic activity is declared or registered)." The average responses are used to capture the extent of perceived informality. The index is reversed here so that a lower WEF index indicates a larger informal economy. Self-employment sample includes 32 LAC economies and 134 EMDEs; WEF sample includes 25 LAC economies and 114 EMDEs.

C. Output informality is based on DGE estimates, in percent of official GDP.

D. Employment informality is based on self-employment as a share of total employment.

The broad-based decline in output informality in recent decades did not occur for employment informality, in part reflecting the effects of trade liberalizations in the 1990s in contexts of heavily regulated labor markets (figure 5.8; chapter 4). In fact, informal employment in countries such as Bolivia, Colombia, Honduras, and Peru increased. Even where employment informality fell overall, the decline was not always widespread. In Brazil and Argentina, two of the largest economies in LAC, middle-aged men, the highly skilled, and full-time workers were the most likely to shift from informal to formal employment during the 2000s (Maurizio 2015).

Correlates of informality in LAC

Informality in LAC is associated with economic and institutional factors such as trade liberalization, worker characteristics, tax policy, and governance.

Trade liberalization. The reduction of trade barriers in LAC in the 1980s and 1990s led to fears that domestic firms in the formal sector would become uncompetitive and shift to the informal sector to reduce costs. The effects of trade liberalization on informality have actually been mixed across countries and different in the short run from the long run (Bosch, Goñi-Pacchioni, and Maloney 2012; Menezes-Filho and Muendler 2011). It has been found that in the presence of labor market rigidities, informal employment may rise in the short term after trade liberalization but not necessarily in the long term (Ponczek and Ulyssea 2018; World Bank 2019b). In Brazil and Peru, trade liberalization was associated with increases in informality as formal firms exited to the informal sector or increasingly hired informal workers, or workers increasingly worked informally (Cisneros-Acevedo forthcoming; Dix-Carneiro and Kovak 2019). In Colombia, trade liberalization was associated with a slight increase in informality, but only before a subsequent reform that increased labor market flexibility (Goldberg and Pavcnik 2003).

Voluntary movement between formal and informal employment. Switching between the formal and informal sectors is common in the largest economies in the region (Bosch and Maloney 2010; Fiess, Fugazza, and Maloney 2008; Perry et al. 2007). This may reflect responses to swings in employment and income opportunities in the formal sector. Other structural factors, such as poor education and skills, could also account for employment informality (Fernández and Villar 2016).

Tax burdens. High tax rates or burdensome tax regulations have encouraged informality in the region (Loayza 1997; Ordóñez 2014; Vuletin 2008). During 2010-18, average corporate and personal incomes tax rates were significantly higher in EMDEs with above-median output informality than in those with below-median output informality (chapter 6). Both corporate and personal income tax rates tend to be higher in LAC than in the average EMDE—indeed, LAC is the only EMDE region where the average personal income tax rate has risen since the early 2000s (figure 5.9).

Institutional quality. In LAC, most of the institutional measures associated with informality are at, or slightly better than, the EMDE average. But there is heterogeneity within the region. LAC economies with weak institutional quality have also tended to be those with high informality (figure 5.9). For instance, higher employment informality in Peru than in Chile has been attributed to poorer governance in Peru (Loayza and Wada 2010). Informality in LAC countries has also been attributed to restrictive business and labor regulations, which discourage firms from entering the formal sector.⁷

⁷ See, for instance, Dougherty and Escobar 2013; Estevão and de Carvalho Filho 2012; Loayza 1997; Loayza, Servén, and Sugawara 2010; and Vuletin 2008.

FIGURE 5.9 Correlates of informality in Latin America and the Caribbean (LAC)

In LAC economies where government effectiveness is poor, output-based informality tends to be high. Self-employment tends to be high where labor market efficiency is low. As of 2019, both corporate and personal income tax rates were higher in LAC than in the average EMDE.

A. Sample includes 17 LAC economies and 49 EMDEs.

B. Sample includes 17 LAC economies and 47 EMDEs.

C. Output informality is based on dynamic general equilibrium (DGE) model estimates, in percent of official GDP. "Above (Below) median" are EMDEs in the LAC region with above- and below-median government effectiveness within the corresponding year (2008 or 2018). Sample includes 32 LAC economies.

D. Employment informality is self-employment as a share of total formal employment. Bars show medians. "Above (Below) median" are EMDEs in the LAC region with above- and below-median labor market efficiency within the corresponding year (2008 or 2018). Labor market efficiency measures flexibility and efficient use of talent. Sample includes 16 LAC economies.

Policy options to address informality challenges in LAC

Designing policies to address informality requires an understanding of its causes and characteristics. These vary considerably in LAC, even within individual countries (Fernández and Villar 2016; Perry et al. 2007). Policies that have been successful in addressing informality in LAC have taken account of these factors, focusing variously on reducing tax burdens, strengthening enforcement of labor regulations, and removing disincentives to formal employment.

Tax policy reforms. Making tax policy less burdensome, by simplifying tax systems or lowering tax rates, could incentivize firms to become formal and increase demand for formal workers. Indeed, a large reduction in payroll tax rates in Colombia in 2012 reduced employment informality in the main metropolitan areas by about 7 percentage points (Fernández and Villar 2016). A reduction and simplification of business taxes in Brazil in 1996 was associated with a significant increase in the incidence of formal firms, and the newly formal firms achieved higher revenue and profits than those operating informally (Fajnzylber, Maloney, and Montes-Rojas 2011). The impact of Brazil's reform on informality varied across economic sectors, however, because of differences in incentives to become formal (Monteiro and Assunção 2012).

Labor market regulations. Tighter enforcement of labor regulations has been effective in reducing informality in the region, through various mechanisms. In Brazil, tighter enforcement of regulations raised wages and output by improving the allocation of workers between the formal and informal sectors (Meghir, Narita, and Robin 2015). More frequent inspections in Brazil also induced some informal workers to become formal (Almeida and Carneiro 2012). Moreover, inspections have been found to be more effective than incentives in convincing firms in Brazil to operate in the formal sector (de Andrade, Bruhn, and McKenzie 2013).

Other regulations. Policy reforms to ease barriers to entering the formal sector have had mixed results. A reform that simplified the process of opening a business in Mexico was successful in increasing the number of registered businesses, but had no impact on informality: the owners of the new businesses were former employees of formal firms, not informal workers (Bruhn 2011; Kaplan, Piedra, and Seira 2011). Financial deepening contributed to a reduction in informality in Uruguay, particularly for women and older workers (Gandelman and Rasteletti 2016).

COVID-19 response. The provision of income support to informal workers during the COVID-19 pandemic has been challenging. In some cases, existing programs have been successfully scaled up, particularly for the lowest-income informal workers. But even where informal workers have been reached, there have been challenges related to coverage (Busso et al. 2020). One lesson is that the provision of social safety nets needs to be more agile, with low barriers to enrollment and provisions for rapid rollout (Arnold, Garda, and Gonzalez-Pandiella 2020).

Middle East and North Africa

On average, MNA has the lowest output and employment informality among all EMDE regions. There is particularly wide divergence within the region, however, consistent with the wide range of per capita incomes across MNA economies (figure 5.10). Output informality in oil importers and non-Gulf Cooperation Council (GCC) oil exporters is well above that in GCC countries, reflecting a sizable presence of agriculture sectors in some countries, as well as histories in some cases of prolonged armed conflict with associated migration, and high reliance on public sector

FIGURE 5.10 Informality in the Middle East and North Africa (MNA)

Informal sector output in the MNA accounts for about one-quarter of official GDP, lower than in other EMDE regions. However, perceptions of informality in MNA have risen somewhat, while they have declined in the median EMDE. Informal activity is relatively low in Gulf Cooperation Council (GCC) economies.

A. Output informality

B. Employment informality and perceptions of informality

C. Informality by economy groups

D. Output informality in selected economies

Sources: International Labour Organization; World Bank; World Economic Forum (2018).

Note: GCC = Gulf Cooperation Council; EMDE = emerging market and developing economies; MNA = Middle East and North Africa. A.B. Blue bars show unweighted averages of the informal economy of the region. Red markers show unweighted averages of all EMDEs and the vertical lines denote the interquartile range of all EMDEs.

A. DGE = dynamic general equilibrium model; MIMIC = multiple indicator multiple causes model. Both models estimate the size of the informal sector as a percent of official GDP. DGE sample includes 15 MENA economies and 122 EMDEs; MIMIC sample includes 16 MENA economies and 124 EMDEs.

B. Self-employment is measured as percent of total employment. The World Economic Forum (WEF) asks the following question: "In your country, how much economic activity do you estimate to be undeclared or unregistered? (1 = Most economic activity is undeclared or unregistered; 7 = Most economic activity is declared or registered)." The average responses are used to capture the extent of perceived informality. The index is reversed here so that a lower WEF index indicates a larger informal economy. Self-employment sample includes 16 MENA economies and 134 EMDEs; WEF sample includes 16 MENA economies and 114 EMDEs.

C. Output informality is based on DGE estimates, in percent of official GDP. Employment informality is self-employment as a share of total employment. Bars and lines show medians of economy averages during 2010-18 in corresponding economy groups. Sample includes 6 GCC economies and 10 non-GCC economies (employment informality) and 6 GCC economies, 2 oil exporters, and 5 oil importers (output informality).

D. Output informality is based on DGE estimates, in percent of official GDP. Bars and diamonds show unweighted period averages. The line shows the unweighted average for EMDEs over the period 2010-18.

employment. Informal activity in these economies absorbs a large proportion of the region's high numbers of unemployed youth. By contrast, employment informality in GCC countries is very low, averaging 3 percent of total employment in 2010-18. This is broadly in line with the high per capita incomes of GCC countries.

Several non-GCC economies have reduced informality over the past two decades. Policies that could be effective in further addressing informality in MNA include building better institutions to spur private sector activity, fiscal reforms to reduce tax burdens and improve revenue collection, increased access to finance, and better education and training for vulnerable groups.

Evolution of informality in MNA

On average in 2010-18, informal output in MNA was equivalent to 22 percent of GDP and informal employment stood at 23 percent of total employment (figure 5.10), substantially below the EMDE averages. Output informality in MNA declined slightly over the past three decades, by 3 percentage points of GDP between 1990-99 and 2010-18, while employment informality fell by 6 percentage points of total employment. Perceptions of informal activity, however, have risen.⁸

In most of the region, declines in informality in recent decades have been very limited (figure 5.10). Some non-GCC economies, such as the Arab Republic of Egypt, Morocco, and Tunisia, have made progress in reducing output informality. Among GCC countries, informality in Qatar has declined the most.

Correlates of informality in MNA

Informality in MNA reflects economic and development challenges ranging from limited private sector activity to armed conflict. Large informal sectors have been associated with weak human capital, low labor productivity and wages, and less inclusive growth. Although informality can provide helpful employment opportunities where the formal sector suffers from severe distortions and governance is poor, the structural, policy, and institutional causes of informality pose challenges for efforts to diversify economies and reduce reliance on commodity production and the public sector.

Economic structure. Low informality in GCC countries in part reflects high reliance on expatriate workers and, in some countries, high public employment of nationals (World Bank 2018a). Urban workers in MNA are less likely to be informally employed than rural workers (Angel-Urdinola and Tanabe 2012).

Conflict. The MNA region has experienced numerous armed conflicts, some prolonged, in recent decades. In Iraq and the Syrian Arab Republic, violent conflicts have severely limited the number of public sector jobs, and many workers have moved into the informal sector for lack of alternatives (Ianchovichina and Ivanic 2014; World Bank 2017). In Jordan and Lebanon, the massive influx of refugees—many of whom are

⁸ Before 2012, perceptions of informal activity in MNA was broadly constant. The recent increase could be due to the Arab Spring in 2011 and associated disruptions of activity and policing and enforcement (for instance, for Egypt and Tunisia; Brown, Kafafy, and Hayder 2017). Informal employment and employment outside the formal sector have also increased in Egypt (Elsayed and Wahba 2019; ILO 2019), while self-employment has remained stable.

unregistered—has enlarged the informal sector, where jobs tend to be labor-intensive and low skilled (Verme et al. 2016).

Governance and business climate. Informality in MNA economies is closely and negatively correlated with the quality of governance (Elbadawi and Loayza 2008). In non-GCC economies, government effectiveness and regulatory quality are substantially worse than EMDE averages, after deteriorating markedly between 2010 and 2018 (figure 5.11). These issues are further compounded by poor public services and burdensome taxation, both of which raise the costs of operating in the formal sector (World Bank 2016).⁹ Such hindrances incentivize firms and workers to remain in the informal sector, where labor productivity is lower.¹⁰

Policy options to address informality challenges in MNA

Widespread informality in non-GCC MNA economies reflects deep-rooted structural challenges, such as high youth unemployment and bloated public sectors that can no longer absorb additional public servants (IMF 2018).¹¹ Public sector employment constitutes more than a quarter of total employment in these economies, on average—well above the EMDE average (figure 5.11). The focus has therefore been on multi-pronged policies that aim to create a more vibrant private sector, especially to encourage small firms to grow and boost the human capital of workers so that they can be productively employed in a reinvigorated private sector. Policies targeting specific vulnerable groups can lessen the negative externalities associated with informality.

Fiscal reforms. Burdensome taxation has been a major constraint on formal sector firms in MNA (Gatti et al. 2014). In non-GCC MNA economies, reforms to align tax systems with international best practices and strengthen enforcement could encourage formalization while also raising revenues. Such reforms could include reducing excessive corporate tax burdens and enhancing revenue collection through harmonized electronic filing systems (for example, Morocco) or the introduction of a value-added tax (for example, Egypt). In Egypt, reduction of the corporate tax burden has been associated with higher revenues through a broader tax base (Gatti et al. 2014).

Building institutions. Public sector effectiveness and regulatory quality in non-GCC MNA economies have deteriorated in the last decade (figure 5.11). Corruption is cited among the biggest hindrances to MNA firm operations, incentivizing firms and workers to operate informally (World Bank 2016). Policies that reduce regulatory costs help increase the movement of informal firms from to the formal sector, while reforms that

⁹ While informal business operations are likely to make lower contributions to government revenues, they may add to utilization of public services, such as provision of infrastructure (Galal 2005).

¹⁰ Based on Enterprise Survey data, a sizable proportion of firms in oil-importing economies, such as Morocco and Tunisia, consider competitors' practices in the informal sector as hindering their own business operations (World Bank 2004).

¹¹ These two issues may be linked. Informality is high among the young, in part reflecting the entrance of workers into public sector jobs at a later age (Angel-Urdinola and Tanabe 2012; Elbadawi and Loayza 2008).

FIGURE 5.11 Correlates of informality in the Middle East and North Africa (MNA)

High informality in non-GCC MNA economies reflects deep-rooted structural challenges, such as high youth unemployment and bloated public sectors that can no longer absorb additional public servants. Policies to improve access to finance and government effectiveness can help shift resources from the informal to the formal sector.

strengthen property rights may assist rural and agricultural-sector populations to access financing (for example, enabling collateralized loans). Policies to promote entrepreneurial activities, such as easing of business licensing requirements, can also facilitate entry of informal workers into more productive jobs in the formal sector.

Increasing access to finance. Access to finance is a more binding constraint on doing business in MNA than in most other EMDE regions (figure 5.11; Farazi 2014). Improving such access, including through stronger legal frameworks and improved

credit protection regimes, can promote formal private sector activity by increasing the transparency of firms to investors and facilitating investment (Straub 2005). Several MNA economies have recently implemented policies in this area, such as new insolvency resolution laws in Egypt, Saudi Arabia, and the United Arab Emirates. The adoption of financial technologies (fintech), such as innovations that automate financial transactions, can also facilitate access to financial services by informal unbanked individuals and SMEs (Lukonga 2018; World Bank 2018b).

Investing in human capital. Policies that expand job training are especially relevant for the young, who are commonly informally employed in MNA, to facilitate their entry into more productive, formal jobs (figure 5.11; Angel-Urdinola and Tanabe 2012). Training programs may be particularly effective if they are coupled with mechanisms to increase women's mobility, which is constrained in the region, and offer a combination of soft and hard skills (figure 5.11). The extension of training to rural areas, where education levels are low, could also be especially beneficial; the region's training programs currently tend to serve higher-income and more educated individuals (Angel-Urdinola, Semlali, and Brodmann 2010). A holistic approach that combines job training with job creation, such as through public-private sector programs, could boost informal workers' earnings (Steel and Snodgrass 2008). In MNA, unemployment rates are higher among university graduates than among low-skilled workers. Thus, education system reforms that are coupled with private sector development (the demand side of the labor market) may be more effective at generating high-quality employment.

South Asia

Employment informality in SAR is pervasive. SAR is home to the highest number of informal workers among the six EMDE regions, accounting for close to two-fifths of the world total. Output informality has declined in recent decades, however. Low labor productivity is a long-standing feature of the region's informal sector.

The pervasiveness of employment informality reflects large artisanal and agricultural sectors and the dominance of micro and small business units, often family businesses. High unemployment among the low-skilled, rural, female, and young populations pushes workers into the informal sector. High informality in the region is also associated with weak institutions and poor business climates. Policies that focus on improving the business environment and addressing skills gaps in vulnerable groups can help promote movement to the formal sector.

Evolution of informality in SAR

Informal employment in SAR (measured by self-employment) was 59 percent of total employment in 2010-18, the second highest among all EMDE regions, and well above the EMDE average of 42 percent. However, employment informality has also declined the most of any region since the 1990s (figure 5.12). Using an alternative measure, lack of basic pension coverage, about 90 percent of the labor force in SAR works informally.

FIGURE 5.12 Informality in South Asia (SAR)

SAR's share of informal employment is the largest among EMDE regions, despite a below-average share of informal output. Employment informality in the region has remained broadly unchanged over the past two decades but output informality has declined rapidly. Persistent low productivity has therefore been a long-standing feature of the region's informal sector.

A. Output informality

A. DGE = dynamic general equilibrium model; MIMIC = multiple indicator multiple causes model. Both models estimate the size of the informal sector as a percent of official GDP. DGE sample includes 7 SAR economies and 122 EMDEs; MIMIC sample includes 7 SAR economies and 124 EMDEs.

B. Self-employment is measured as percent of total employment. The World Economic Forum (WEF) asks the following question: "In your country, how much economic activity do you estimate to be undeclared or unregistered? (1 = Most economic activity is undeclared or unregistered; 7 = Most economic activity is declared or registered)." The average responses are used to capture the extent of perceived informality. The index is reversed here so that a lower WEF index indicates a larger informal economy. Self-employment sample includes 7 SAR economies and 134 EMDEs; WEF sample includes 6 SAR economies and 114 EMDEs.

C. Output informality is based on DGE estimates, in percent of official GDP.

D. SAR sample includes 7 economies.

Although there is evidence that the COVID-19 pandemic has been accompanied by a movement of formal workers into the informal sector, informal workers were more vulnerable to loss of employment in the early stage of the pandemic, when lockdown measures were most stringent (World Bank 2020d). In India, lockdown measures are estimated to have tripled the urban unemployment rate in the early stages of the pandemic. The income losses associated with these lost jobs were exacerbated by the fact that some 60-85 percent of urban workers had no access to social protection benefits,

making reaching them through relief programs more challenging (Bussolo, Kotia, and Sharma 2021; Dhingra 2020).

Output informality in SAR has also fallen, to 29 percent of official GDP in 2010-18 from 38 percent in 1990-99—the largest decline of the six EMDE regions. Survey-based measures of perceptions of informal activity also indicate a decline.

Sri Lanka has the highest output informality in the region, at 38 percent of GDP in 2010-18, while India has the lowest, at 18 percent (figure 5.12). India has the highest employment informality, however, of 77 percent of total employment in 2010-18, reflecting large disparities in labor productivity between the formal and informal sectors.

Correlates of informality in SAR

High employment informality in SAR is associated with weak human capital development, poor business conditions and limited access to financial resources. Informality has adverse implications for poverty and inequality reduction, especially where fiscal revenues available to fund development objectives are limited.

Human capital. SAR has the second lowest average years of schooling among EMDE regions, behind only SSA (Barro and Lee 2013).¹² Low levels of education limit opportunities for employment in the formal economy. Conditions in slums, home to 130 million South Asians, entrench large education gaps (Ellis and Roberts 2016). In Bangladesh, for example, the net school enrollment rate of children living in informal communities is 15 percentage points below the national average (Kabir and Parajuli 2016).

COVID-19 impact. The negative effects of the COVID-19 pandemic on human capital accumulation may have implications for future informality in SAR. A decline in the duration of schooling during the pandemic may ultimately push more of the labor force into the informal sector, where they will face lower earnings. It is estimated that average lifetime earnings in South Asia will decline by 5 percent because of the pandemic (Azevedo et al. 2020; World Bank 2020d).

Worker characteristics. South Asia's informal labor force consists predominantly of low-skilled, rural, female, or young workers (Goldar and Aggarwal 2012; Gunatilaka 2008; Parajuli 2014). Such worker characteristics contributed to a wider labor productivity gap between formal and informal sectors in SAR than in other EMDE regions (Loayza 2018). For many, the informal sector is the only option for earning a livelihood. In Pakistan, the characteristics of individuals, such as older age and higher levels of education, have been found to be more predictive of formal employment than the institutional environment (Williams, Shahid, and Martinez 2016).

¹² Average years of schooling in Afghanistan, Nepal, and Pakistan were lower than the SSA average in 2010, the most recent year of available data.

FIGURE 5.13 Correlates of informality in South Asia (SAR)

Weak control of corruption, low government effectiveness, and heavy tax burdens have likely contributed to high employment informality in SAR. Unemployment is higher among women, who represent a larger share of informal workers than men.

B. The index represents the distance to the frontier in the World Bank's *Doing Business*. An economy's ease of doing business score is calculated on a scale from 0 to 100.

C. The index represents the distance to the frontier of the ease of paying taxes indicator in the World Bank's *Doing Business*. The value is subtracted from 100 to reflect tax burden.

D. Bars show unemployment rates for the labor force ages 15 and above during 2010-20.

Business climate. Over the past decade, SAR has suffered greater corruption and weaker government effectiveness than EMDEs on average (figure 5.13). The business environment in SAR—such as the burden of tax rates and compliance, labor regulations, and the ease of starting a business—is also less favorable than in the average EMDE, and has been associated with high informality (Goldar and Aggarwal 2012; FICCI 2017; Waseem 2018).

Policy options to address informality challenges in SAR

Policies to address the challenges related to informality in SAR could prioritize addressing weak human capital in vulnerable groups and improving access to finance and public services. Also important, including for the creation of a more conducive

climate for private sector development, would be strengthening governance and reducing regulatory burdens.

The COVID-19 pandemic has highlighted structural problems in the informal sector in South Asia (Kesar et al. 2021; World Bank 2020d). In the short run, policy makers can provide relief to the informal sector, and in the long run increase the inclusivity of universal social protection systems.

Investing in human capital. Unemployment is particularly high among young, low-skilled, female, and rural workers (figure 5.13). These groups often seek employment in the informal sector. Policies targeting training and education of these groups, especially in rural areas, could help their transition to formal employment (Khera 2016).

Increasing access to resources. Greater access to credit for informal workers could encourage formalization in South Asia (Beck and Hoseini 2014; Ghani, Kerr, and O'Connell 2013). Expanding access to microfinance has led to increasing investment and productivity in the informal sector (Donou-Adonsou and Sylwester 2017; Imai and Azam 2012). High-quality public services can also provide an incentive for informal firms to become formal in order to access them.

Building institutions. There is significant room for improvement in SAR's business environment, including improving government effectiveness and controlling corruption. Measures to reduce regulatory burdens would also improve the business climate and foster growth (FICCI 2017). This could reduce informality by reducing the costs of entry to, and operating in, the formal sector. Enhanced monitoring and enforcement, including of tax regulations, could help discourage informality (Ilzetzki and Lagakos 2017). In India, the recent introduction of a Goods and Services Tax is expected to encourage formalization of activity.

Sub-Saharan Africa

Informality in SSA is very high by multiple measures. In some countries, informal employment exceeds 80 percent of total employment. In others, informal output is equivalent to more than half of official GDP. SSA had the highest employment informality of the six EMDE regions in 2010-18, and along with ECA and LAC, also had the highest output informality.

Numerous factors related to underdevelopment are associated with informality in SSA, including weak institutions, large rural and agricultural sectors, armed conflicts, and low human capital. The high incidence of poverty and inequality is also closely linked to the prevalence of large informal sectors.

Governments in SSA have struggled with how to address high levels of informality. There is a growing recognition of the key role of the informal economy in the region's development, and of the potential of the resources it employs if policies were more attuned to their mobilization.

Evolution of informality in SSA

Informal output in SSA was 36 percent of official GDP, on average, in 2010-18, the highest among EMDE regions and slightly above the shares in LAC and ECA (figure 5.14). Informal employment (measured by self-employment), at 62 percent of total employment, was also the highest among the EMDE regions. Alternative measures of informality, such as the share of labor without pension coverage (above 90 percent) and perceptions of informal activity, are also among the highest of EMDE regions.

Over the past two decades, both output and employment informality in SSA have fallen somewhat, by 5 and 6 percentage points, respectively. Relative to other EMDE regions, the decline in employment informality was large, whereas the fall in output informality was broadly in line with the EMDE average. That said, several SSA countries have made more significant progress in lowering output informality (figure 5.14).

Informality is higher in low-income countries (LICs), fragile states, and commodity exporters. Informal employment exceeded 85 percent of total employment, on average, in countries such as Benin, Burundi, and Madagascar during 2010-18, whereas it was less than 20 percent in countries such as Mauritius and South Africa. Among sub-regions, central and western Africa had the highest average shares of informal employment during 2010-18, at 80 percent and 74 percent, respectively, compared to 50 percent in southern Africa.

Correlates of informality in SSA

High informality in SSA reflects wide-ranging economic and development challenges, including poor institutions, labor and product market rigidities, armed conflict, limited access to resources, and a dearth of skilled labor (Lince 2011; Xaba, Horn and Motala 2002).

Fragility and conflict. As of 2021, SSA hosts all but six of the world's 29 LICs and more than half of the world's 39 fragile states. In general, informality is higher in low-income SSA countries—especially in fragile states with weak state capacity—than elsewhere in the region. Economic disruptions related to conflict and violence have been an important factor forcing people to earn their livelihoods in the informal economy (Heintz and Valodia 2008).

Economic structure. In commodity-exporting countries, the capital-intensive mining sector creates few formal employment opportunities (and artisanal mining creates informal employment opportunities). Moreover, most economies in SSA have large agricultural sectors that have high rates of self-employment. In non-agricultural sectors, there is also considerable self-employment in labor-intensive services, such as street vendors, craftsmen, and home-based activities (Fox and Sohnesen 2012). Rural-to-urban migration and increased labor force participation, especially among women, have been mostly absorbed by the informal sector (Kessides 2005). In countries where social norms restrict the mobility of women, their only employment options are in the informal sector (ILO 2009).

FIGURE 5.14 Informality in Sub-Saharan Africa (SSA)

SSA has the highest output and employment informality of the six EMDE regions, although both measures have fallen somewhat in recent decades. Informality is highest in western and central Africa, low-income countries, fragile states, and commodity exporters.

C. Output informality is based on DGE estimates, as percent of official GDP.

D. World Bank classifications. Bars show unweighted group averages over the period 1990-2018. Lines show unweighted averages for SSA over the same period.

Regulatory burden and governance. SSA has considerably heavier regulatory burdens than other EMDE regions (figure 5.15). Burdensome regulations such as lengthy business registration processes, cumbersome procedures for filing taxes, costly documentary compliance for exports and imports, rigid labor regulations, and high taxes can make it prohibitively expensive to operate in the formal economy (Mbaye and Benjamin 2015). SSA also has considerably weaker governance and institutions than other EMDE regions, which can result in failures in enforcing regulations and containing corruption and an environment in which informal enterprises can easily conceal their activities and evade taxes.

FIGURE 5.15 Correlates of informality in Sub-Saharan Africa (SSA)

Low human capital, limited access to resources, heavy regulatory burdens, and weak governance are potentially important drivers of informality in SSA.

 A.C.D. Blue bars are +/- 1 standard deviation of SSA mean.
 A.B.F. GDP per capita is measured as thousands of 2011 PPP dollars (in logarithm). Life expectancy at birth is in years (in tens). Poverty is the headcount at \$1.90 per day (2011 PPP) as percent of population. Trade openness is the sum of exports and imports as a share of GDP. Financial development is proxied by private credit as a share of GDP. Tax burden is the total tax rate. Investment is gross fixed capital formation as a percentage of GDP. Tax revenue is expressed as a share of GDP.
 B.E.F. The orange diamonds show the coefficient estimates and the blue bars denote the 90 percent confidence intervals. Ordinary least squares (OLS) estimators are applied, with country means over the sample period used for both the dependent and independent variables. The share of self-employment in total employment is the dependent variable in panels B and E and the independent variable in panel F. The coefficient estimate measures the effect on the dependent variable of a unit change in the independent variable. Sample includes 37 SSA countries.
 C. The index represents the distance to the frontier in the World Bank's *Doing Business*. An economy's ease of doing business score is calculated on a scale of 0 (lowest performance) to 100 (best performance). Data are for 2004-18.
 D. Data are for 1996-2018.
 E. The correlates are the distance to frontier in *Doing Business* (for 2004-16) and scores from the Worldwide Governance Indicators (for 1996-2018). The coefficients for the governance and regulatory indicators are in hundredths.

Labor productivity. Differences in labor productivity between formal and informal sectors are large: value added per worker in informal firms is only 14 percent that in formal firms in the median SSA country, lower than the corresponding ratio in other EMDEs (La Porta and Shleifer 2014). Although Enterprise Surveys conducted in SSA indicate that practices of competitors in the informal sector are only the third biggest obstacle to the activities of formal firms (after access to electricity and finance) they are more problematic in SSA than in other EMDE regions (figure 5.16; Dinh, Mavridis, and Nguimkeu 2010; La Porta and Shleifer 2016; Nguimkeu 2014).

COVID-19 impact. The large pool of informal workers in SSA, already highly vulnerable to economic shocks, was poorly positioned to withstand the unprecedented supply and demand shocks caused by the COVID-19 pandemic. Further, evidence suggests that the presence of large informal sectors in the region, where workers gather in close proximity to one another, exacerbated the spread of COVID-19 (Nguimkeu and Okou 2020, 2021).

Policy options to address informality challenges in SSA

While informality is more pervasive in SSA than in other EMDE regions, the environment is conducive to a policy push to shift informal to formal activity. More SSA formal firms started out as informal and the duration of their informality was shorter than in other EMDEs (figure 5.16). Population surveys in SSA also tend to show a more positive attitude toward starting a business than surveys in other EMDE regions, despite a higher proportion of entrepreneurs who became such out of necessity. Thus in one survey, 65 percent of respondents believed that they had the required skills and knowledge to start a business, 59 percent indicated that they saw good opportunities to start a firm, and 43 percent intended to start a business within three years. This entrepreneurial spirit, despite high regulatory burdens, may make the informal sector a reservoir of untapped economic potential if allowed to flourish (de Soto 1989; Grimm, Knorringa, and Lay 2012).

Policy makers are focusing their efforts on a combination of strategies aimed at making work more skilled and more productive. Investing in human capital, including increasing the duration of schooling and improving learning outcomes, is a critical pillar in the region's development strategy.¹³ Other policies that have been successful in addressing informality have focused on increasing access to resources, such as leveraging technology to make banking accessible to the general public and bridging small informal firms to formal markets (Benhassine et al. 2018; Nguimkeu and Okou 2019). Building better institutions would also help to foster a more conducive business environment, encouraging informal firms to operate in the formal sector and incentivizing formal firms to invest and create more job opportunities.

¹³In Kenya, for example, improved managerial skills and new marketing channels induced by competition helped metalwork enterprises in the Kariobangi Light Industries grow and transition to the formal economy (Sonobe, Akoten, and Otsuka 2011). The local government provided little support other than designating an area for these artisans to operate, but that proved sufficient.

FIGURE 5.16 Informality indicators and entrepreneurial conditions in Sub-Saharan Africa (SSA)

In SSA, on average, more than 80 percent of surveyed firms lack formal registration, while about three-quarters of formal firms face competition from firms in the informal sector. There are indications of widespread entrepreneurial ambition in SSA, but potential entrepreneurs are deterred from entering the formal sector by low human capital, limited access to resources, heavy regulatory burdens, and weak governance.

A. Informal competition

B. Formal registration of firms

C. Entrepreneurship attitudes

D. Entrepreneurial framework conditions

Sources: Global Entrepreneurship Monitor; World Bank (Enterprise Surveys).

Note: EMDE = emerging market and developing economies; Other EMDE = EMDEs excluding those in Sub-Saharan Africa; SSA = Sub-Saharan Africa. Blue bars are +/- 1 standard deviation of SSA mean.

A.B. "Informal competitors" shows the percent of firms competing against unregistered or informal firms. "Informality constraint" shows the percent of firms identifying practices of competitors in the informal sector as a major constraint. "Formal registration" shows the percent of firms formally registered when they started operations in the country. "Years unregistered" shows the number of years firms operated without formal registration. Data for 2006-18.

C. "Opportunity" is the percent of population ages 18-64 who see good opportunities to start a firm in the area where they live. "Capability" is the percent of population ages 18-64 who believe they have the required skills and knowledge to start a business. "Intention" is the percent of population ages 18-64 (individuals involved in any stage of entrepreneurial activity excluded) who are latent entrepreneurs and who intend to start a business within three years. "Motivation" is the percent of those who are either a nascent entrepreneur or owner-manager of a new business that are improvement-driven and opportunity-motivated, divided by the percentage that is necessity-motivated (a lower ratio indicates a higher proportion that is necessity-driven). Data for 2000-19.

D. Scores range from 1 to 9. A higher score represents better perceived condition. "Basic training" is the extent to which training in creating or managing small- and medium-sized enterprises (SMEs) is incorporated within the education and training system at primary and secondary levels. "R&D" is the extent to which national research and development will lead to new commercial opportunities and is available to SMEs. "Market openness" is the extent to which new firms are free to enter existing markets. "Business infrastructure" is the presence of property rights, commercial, accounting and other legal and assessment services and institutions that support or promote SMEs. "Physical infrastructure" is the ease of access to physical resources, communications, utilities, transportation, land, or space at a price that does not discriminate against SMEs. Data for 2000-19.

Investing in human capital. Policies to improve human capital can be prioritized. Fewer than 20 percent of primary school students in SSA pass a minimum proficiency threshold in learning assessment, the lowest among EMDE regions (World Bank 2019a). Teachers are often absent from classrooms. The ensuing learning deficiencies compound over time and eventually appear as a weakly skilled labor force. Although technically and politically difficult, efforts to improve learning outcomes are essential. There is also a need to address issues related to health care. COVID-19 is likely to set back human capital further, by disrupting schooling and livelihoods. To cushion the negative effects of the pandemic, concessional financing and enhanced domestic resource mobilization will be critical to ensure sufficient investment in human capital, as well as green energy and digital infrastructure, amid elevated public debt (World Bank 2021).

Improving labor productivity. Small informal firms, lacking in human capital, cannot be expected to raise the productivity of their labor forces just by registering (La Porta and Shleifer 2016). Large informal firms are likely to resemble formal firms much more than their small informal counterparts: labor productivity differentials between large informal firms and formal ones tend to be minor (Benjamin and Mbaye 2012). In west Africa, the largest and fastest growing sectors are dominated by large, informal firms. This argues for policies to encourage small firms to grow into larger, more productive ones, through skills upgrading and better access to inputs and resources such as business development services, transport and communications connectivity, financial services, health services, land and property rights, infrastructure, digital technology, and product markets (Nguimkeu and Okou 2019; Oosthuizen et al. 2016; World Bank 2021).¹⁴ As these firms become more productive, with higher quality products, they may be able to participate in formal-sector supply chains (La Porta and Shleifer 2016). For large firms or those that voluntarily remain informal to evade taxes or avoid labor codes, incentives to encourage formal registration can be combined with tighter enforcement (Mbaye and Benjamin 2015).

Building institutions. Regulatory and institutional reforms to build public trust can strengthen incentives for firms to operate formally (Mbaye and Benjamin 2015). This includes improving the business environment by removing unnecessary regulatory barriers, strengthening monitoring and enforcement capabilities, combatting corruption, and upholding legal and judicial systems. These policies apply equally to formal firms as an enabling environment is critical for investment and employment generation. Improving macroeconomic stability with sound fiscal and monetary policy frameworks is also essential.

Stakeholder engagement. Governments can actively engage with the informal community to put in place the conditions for informality to end. This can involve educating informal firms on the benefits of formal registration, providing information on formalization and the procedures involved, participating in social dialogues to

¹⁴ For example, training programs in Côte d'Ivoire have had significant positive economic results for informal workers in the agricultural and electronics sectors (Verner and Verner 2005).

understand pressing issues for informal firms, customizing household surveys to better capture important aspects of informality, and collaborating with informal actors to design and implement effective development policies.

Conclusion

The varied nature of informality in EMDEs indicates the need for policy mixes that are appropriate to each economy's circumstances. Cross-economy experiences also highlight the importance of the right policy mix. Policies that have been successful in addressing informality fall broadly into four categories: investing in human capital, improving access to resources, easing regulatory and tax burdens, and strengthening governance.

- *Investing in human capital.* In Pakistan and Côte d'Ivoire, for example, training programs boosted worker income and firm revenue in the informal sector (Burki and Abbas 1991; Verner and Verner 2005).
- *Improving access to resources.* In Kenya and Bangladesh, providing informal firms with better access to markets or finance helped increase firm profitability and investment, easing transition to the formal sector.¹⁵
- *Ease regulatory and tax burdens.* Policies to reduce tax rates and simplify tax systems have incentivized firms to transition to the formal sector in countries such as Colombia, Egypt, Mexico, and Russia.¹⁶
- *Strengthen governance.* In Georgia, during 1996-2016, the transition to a market economy brought significant improvements in government effectiveness, control of corruption, and law and order (World Bank 2019b). This was accompanied by a steep decline in informality.

The COVID-19 pandemic has taken an especially heavy toll on informal workers, who have not only faced severe income losses, but have also been difficult for social safety nets to reach to offset some of the income losses. Restrictions on physical interaction and mobility, to impede the spread of the virus, have been difficult to enforce for informal workers because many already live on the cusp of poverty, in turn blunting the public health benefits of lockdowns (Alon et al. 2020).

With good policies, effective enforcement of sensible regulations can help reduce the presence of the informal sector (Loayza 2018). In Brazil, labor inspections helped induce informal workers and firms to formalize (Almeida and Carneiro 2012; de Andrade, Bruhn, and McKenzie 2013). In ECA, better control of corruption reduced the extent of informal activities in the countries that joined the EU in the mid-2000s (Fialová and Schneider 2011). In SSA, policies have focused on unlocking the latent economic

¹⁵ See, for instance, Donou-Adonsou and Sylwester 2017; Imai and Azam 2012; and Sonobe, Akoten, and Otsuka 2011.

¹⁶ See, for instance, Bruhn 2011, Fernández and Villar 2016, Gatti et al. 2014, and Slonimczyk 2012.

potential of the informal sector through investing in human capital and improving access to resources to increase labor productivity. Such policies offer a pathway for informal firms to improve product quality and participate in formal-economy supply chains. In contrast, in ECA, LAC, and non-GCC MNA economies, successful policies have centered around easing regulatory and tax burdens and building more effective and accountable institutions—in particular, strengthening enforcement and reducing corruption. Supportive macroeconomic, structural, and social policies—such as reducing labor market rigidities and enhancing public service delivery and social protection—can ease the implementation of these reforms and facilitate smoother transitions to the formal sector.

The importance of comprehensive strategies, based on thorough economy-specific diagnoses, merits emphasis. In some instances, well-intentioned policies have turned out to aggravate the problems associated with informality. Often these policies were implemented in isolation without complementary measures. For example, trade liberalization reforms were followed by greater informality in some LAC countries, but when the reforms were accompanied by supporting policies, such as more flexible labor market regulations and well-designed social safety nets, the outcomes were more favorable.

Digital platforms offer governments opportunities to reduce regulatory burdens, strengthen tax administration, and improve the coverage of social protection programs.¹⁷ In Georgia, for example, successful tax reforms were accompanied by the introduction of an electronic tax filing system, which led to improved efficiency, a doubling of the tax-revenue-to-GDP ratio, and a reduction in employment informality by 8 percentage points between 2004 and 2011 (Akitoby 2018). In response to the COVID-19 pandemic, new online platforms (Thailand and Brazil) and new mobile payment devices (Morocco) have been utilized to help governments expand the coverage of existing social protection programs to reach informal workers (World Bank 2020e).

PART III

Policies

CHAPTER 6

Tackling Informality: Policy Options

Overcoming the challenges of informal economic activity requires a combination of policies tailored to economy-specific circumstances. In countries where informality is predominantly a reflection of poor governance, an appropriate policy package could streamline regulatory and tax frameworks while improving the efficiency of public revenue collection and regulatory enforcement as well as strengthening public service delivery to bolster tax morale. In countries where informality is predominantly a reflection of underdevelopment, an appropriate policy package could include measures to expand access to finance, markets, and inputs to foster firm productivity and growth; better education to facilitate formal sector employment; and enhanced safety nets to cushion household risks. Several such policy improvements have been associated with sustained declines in informality.

Introduction

Widespread informality is a common policy challenge in emerging market and developing economies (EMDEs). Theoretical models present two major reasons for the emergence of informal economic activity: lack of development (Harris and Todaro 1970; Loayza 2016), and poor governance (de Soto 1989). These two reasons suggest different policy approaches to address informality. The former refers to factors such as an inability of an urban, modern, formal sector to absorb rural migrants; limited financial development to provide finance for formal sectors; and insufficient human capital that prevents workers from finding jobs in the formal sector.¹ The latter refers to factors such as excessively burdensome tax and regulatory frameworks that encourage firms to remain informal, excessive labor regulations that increase the cost of formal employment, and poor governance and regulatory quality that discourage formal participation (chapter 2). The former reason emphasizes the inability to benefit from participating in the formal sector, while the latter emphasizes the costs associated with formal-sector participation.²

Many EMDE governments have implemented a wide range of policy reforms in the past few decades that may have helped to reduce informality (figure 6.1; Jessen and Kluge

Note: This chapter was prepared by Franziska Ohnsorge and Shu Yu. Research assistance was provided by Hrisyana Doytchinova and Lorez Qehaja.

Note: See World Bank Doing Business database for reform details. EMDEs = emerging market and developing economies; EAP = East Asia and Pacific; ECA = Europe and Central Asia; LAC = Latin America and Caribbean; MNA = Middle East and North Africa; SAR = South Asia; SSA = Sub-Saharan Africa.

A.B. For an average economy, the number of policy reforms that have been implemented after year 2008 and are regarded as "improvement" in the ease of doing business or "neutral" (which only applies to "labor market regulation") by Doing Business 2008-18.

C.D. For an average economy, the average number of policy reforms per year that have been implemented during 2008-10 in comparison to the annual average number of reforms conducted during 2016-18 (shown in bars).

E.F. Bars show the shares of economies with improved control of corruption (the ease of doing business) between 2010 and 2018.

2021).³ These reforms have often been implemented to either increase the benefits of formal-sector participation or reduce the costs of formal activity. For instance, both corporate and personal income tax rates in EMDEs have been reduced, from 37-39 percent on average in the early 1990s to around 24 percent in 2019 (Végh and Vuletin 2015). Time spent on paying taxes was cut by about one-third in EMDEs between 2006 and 2020. Value-added taxes, which can lower tax burdens through a refund on input taxes, had been adopted in 71 EMDEs by 2020 (World Bank 2020a). Access to financial services has broadened, with access to automatic teller machines (ATMs) per 100,000 adults and the share of the population with an account at a financial institution both increasing by more than 50 percent between 2010 and 2018. Over the same period, one-third to two-thirds of EMDEs improved their governance and institutional quality.

A review of past policy reforms indicates that some reforms had unintended consequences for informality. Policy reforms often had more benign effects on informality when they were implemented in a supportive institutional and macroeconomic environment. For instance, trade liberalization programs were often associated with greater informality in the short term—unless they were accompanied by greater labor market flexibility and an upgrading of skills in the labor force (Goldberg and Pavcnik 2003; McCaig and Pavcnik 2015; World Bank 2019 b).

The current pandemic has provided a reminder of the developmental challenges posed by the informal sector. Informal participants have suffered more adverse economic and health consequences from COVID-19 than their formal counterparts (box 2.1). The untapped potential of informal sectors, if harnessed to boost income growth and resilience, can help EMDEs build back better from the severe global recession of 2020. This is especially important against the backdrop of a steady decline in potential growth, the growth an economy can sustain at full employment and capacity, over the past decade as all fundamental drivers of growth weakened (World Bank 2018; World Bank 2020b). Specifically, chapter addresses the following questions:

- Which fiscal measures can help reduce informality?
- Which other policies can help reduce informality?
- What should be the elements of a comprehensive policy package to tackle informality?

Contributions. The chapter makes the following contributions to the literature. First, it offers a systematic review of policies that could affect informality, ranging from fiscal policies to labor market regulations and policies to encourage financial development. It covers both policies that are intentionally designed to encourage formalization and ones that could incidentally affect the informal sector.

³ Some of these reforms had their roots in the “Washington Consensus” (Birdsall, de La Torre, and Caicedo 2010; Naim 1999; Williamson 2000).

BOX 6.1 Financial development and the informal economy

Financial development reduces the costs of accessing external financing and thus incentivizes firms and households to invest, including in higher-productivity projects. It also incentivizes participants of the informal sector to join the formal sector. In emerging market and developing economies (EMDEs) with above-median informality, a significantly larger share of firms rely on internal finance and identify access to finance as a major business obstacle than in EMDEs with below-median informality. Also, in EMDEs with more prevalent informality, a significantly smaller share of households have access to commercial bank branches, automated teller machines (ATMs), and credit. Over the past three decades, growing access to financial services and credit has coincided with a falling share of the informal economy.

Introduction

In recent decades, much research has been devoted to understanding the determinants of informal economic activity, including the role of financial development (Loayza 2018; Ulyssea 2020). Financial development can influence firms' and individuals' choices to engage in informal activity and may also, conversely, be affected by the level of informality (for instance, Capasso and Jappelli 2013; Elgin and Uras 2013; Straub 2005). Easier access to non-cash-based payments—whether via mobile phones, cards, or online—can improve the government's ability to reach and support informal participants during a recession like COVID-19 (Fang, Kennedy, and Resnick 2020; World Bank 2019c).^a

Firms in the informal sector are typically characterized by small scale, low capital-to-labor ratios, lack of investment, a low propensity to implement new, and even high-return, technologies, and unskilled managers (Capasso and Jappelli 2013; Dabla-Norris, Gradstein, and Inchauste 2008; Quintin 2008). By influencing firms' behavior, financial development can encourage capital accumulation and productivity improvements, and thus enhance long-run economic growth, particularly in the presence of informality (Antunes and Cavalcanti 2007).

Against this background, this box addresses the following questions:

- What links between informality and financial development have been identified by the literature?
- How does financial development differ between EMDEs with high and low informality?

Note: This box was prepared by Salvatore Capasso, Franziska Ohnsorge, and Shu Yu.

a. See Fang, Kennedy, and Resnick (2020) for detailed examples.

BOX 6.1 Financial development and the informal economy (continued)

- How has financial development in EMDEs evolved?

The box examines the nexus between financial development and informality both theoretically and empirically. It first provides a short literature review on the channels through which limited financial development can encourage informality, followed by a summary of existing empirical evidence. It then uses both descriptive statistics and regression analysis to show that greater informality is associated with less financial development, and that better access to finance is associated with lower informality. The conclusion offers policy recommendations.

Lessons from the literature

Theoretical models suggest that financial development reduces informality, while the existence of informality could also hinder financial development. Such theoretical findings are supported by empirical studies.

Theoretical models. As informal participants hide all or part of their income and wealth from the authorities, they face high costs of providing collateral or signaling their profitability to lenders and are often credit-rationed (Blackburn, Bose and Capasso 2012; Capasso and Jappelli 2013). The choice of operating formally or informally thus involves a trade-off between higher financial costs, as well as restricted access to public goods, and the benefits of lower tax and regulatory burdens (Franjo, Pouokam, and Turino 2020; Straub 2005). This trade-off can be faced at the level of the firm or household (extensive margin) or at the level of individual transactions within a firm (intensive margin).

Theory predicts that as financial markets develop, the size of the informal sector will decrease. Financial development, which involves innovations ranging from the emergence of new and more efficient monitoring and screening technologies to more intermediated funds, typically reduces the average costs of accessing financial resources and incentivizes firms and entrepreneurs to operate formally. Several mechanisms have been explored.

- *Lower collateral requirements.* By improving screening and monitoring technologies, financial development will tend to reduce the minimum collateral required for borrowing, which will tend to attract entrepreneurs into the formal sector (Straub 2005).
- *Stronger legal enforcement.* By strengthening financial contract enforceability, financial development can lower credit costs, which will also tend to attract entrepreneurs into the formal sector (Amaral and Quintin 2006; Antunes and Cavalcanti 2007; Quintin 2008).

BOX 6.1 Financial development and the informal economy (continued)

- *Expanding pool of formal finance.* By expanding the pool of formal-sector funding, financial development can lower the relative cost of formal finance and attract entrepreneurs into the formal sector (Blackburn, Bose, and Capasso 2012; Capasso and Jappelli 2013).
- *More efficient tax auditing.* Financial development can facilitate the enforcement of tax compliance, which is likely to discourage informal activity (Guo and Hung 2020).

Conversely, some studies point to informality as holding back financial development, through several channels.

- *Tax evasion.* Tax evasion, which is often at the core of informality, erodes government revenue bases. Countries with pervasive tax evasion have often used financial transaction taxes to boost revenues. These taxes increase financial intermediation costs and may slow financial development (Elgin and Uras 2013; Roubini and Sala-i-Martin 1992, 1995).
- *Higher bank monitoring costs.* Where informality is prevalent, the lack of formal, declared incomes and assets may force banks to incur higher screening and monitoring expenses. This raises borrowing costs (Capasso, Monferrà, and Sampagnaro 2015).

Empirical evidence. Several measures of financial development have been found to be statistically significantly associated with smaller informal activity (Bittencourt, Gupta, and Stander 2014; Bose, Capasso, and Wurm 2012; Gatti and Honorati 2008). The empirical association has been robust to different model specifications and estimation methodologies (See table 6.1 for a detailed summary).

- *Firm-level evidence.* Firms that rate financing as a major obstacle to their businesses have, on average, a 16 percent probability of hiding at least 50 percent of their sales, whereas this probability drops below 6 percent for firms that consider financing to be a minor obstacle (Dabla-Norris, Gradstain, and Inchauste 2008). More tax-compliant firms have reported significantly easier access to credit, and this relationship was stronger in more formalized economies (Gatti and Honorati 2008).
- *Household-level evidence.* Italian households reported greater informal activity, especially in the construction sector, in regions with weaker financial development (Capasso and Jappelli 2013).
- *Cross-economy evidence.* Among 137 economies during 1995-2007, both greater efficiency and depth of the banking sector were associated with

BOX 6.1 Financial development and the informal economy (continued)

significantly lower informality (Bose, Capasso, and Wurm 2012). Among 150 economies during 1980-2009, faster broad money growth and a smaller differential between lending and deposit interest rates were associated with statistically significantly smaller informal economies, even when controlling for institutional quality and central bank independence (Bittencourt, Gupta, and Stander 2014).^b

Stylized facts

Firms and workers in the informal sector have less access to credit and financial services in EMDEs with above-median informality than in EMDEs with below-median informality.

Methodology and data. A sample of 122 EMDEs for 1990-2018 (or the latest available year) is split into those with above-median and below-median shares of informality by output (as proxied by the dynamic general equilibrium model-based share of informal output in official GDP) and employment (proxied by the share of self-employment in total employment).^c Financial development is proxied, first, by firms' reported access to bank credit and capital markets, their difficulty in accessing credit and the share of internal finance used in investment. Second, at the household level, financial development is proxied by the number of commercial bank branches, automated teller machines (ATMs), and bank credit as well as account ownership and reported use of mobile payment services. Data are available from World Bank Enterprise Surveys, the World Bank's Global Financial Development Database, and the World Development Indicators. In addition, the International Monetary Fund (IMF)'s Financial Development Index and its sub-components are used as proxies for overall financial development and for development in "financial institutions" and "financial markets".^d Simple averages of the financial development indicators for EMDEs with above-median informality and those with below-median

b. Several studies have found nonlinear relationships between informality and financial development. The impact of financial development on informality is greater in more financially developed economies or when GDP exceeds a certain level (Canh and Thanh 2020; Gharleghi and Jahanshahi 2020) or may even be inverse-U-shaped (Elgin and Uras 2013).

c. The results from output informality and employment informality are largely consistent. This box mainly relies on results from output informality.

d. The "financial markets" development index captures access to, and depth and efficiency of, an economy's stock and debt markets, which is less relevant for informal participants in EMDEs. The "financial institutions" development index measures how developed financial institutions are in terms of their depth (size and liquidity), access (ability of individuals and companies to access financial services), and efficiency (ability of institutions to provide financial services at low cost and with sustainable revenues).

BOX 6.1 Financial development and the informal economy (continued)

informality (grouped above) are tested for statistically significant differences. There is no presumption of causality going either from financial development to informality or vice versa.

Firms. Firms in the informal sector have reported more restricted access to credit from the banking sector and capital markets, which limits their ability to invest, including in productivity-enhancing new technologies (Capasso and Jappelli 2013; D’Erasmus 2016; Ferreira-Tiryaki 2008). In the average EMDE with above-median output informality, 36 percent of firms identified access to finance as a major constraint—about 9 percentage points more than in other EMDEs (figure B6.1.1). Firms also rely more on internal finance for operating, starting, or expanding firms in EMDEs with more pervasive informality (Farazi 2014). On average in EMDEs with above-median informality, 75 percent of firms depend on internal finance to invest and 19 percent of firms can utilize bank funds to fulfill their investment needs, compared with 68 percent and 29 percent of firms, respectively, in the average EMDE with below-median informality.

Households. Households in EMDEs with below-median informality have access to significantly more commercial bank branches, ATMs, and credit than those in EMDEs with above-median informality (figure B6.1.1). About 50 percent of the population in EMDEs with below-median informality own an account at a financial institution or recently used a mobile money service—about 17 percentage points more than in EMDEs with above-median informality.

Evolution of financial development and its implications

EMDE financial systems have deepened and financial access has broadened over the past three decades. This has coincided with a steady decline in the shares of informal output and employment.

Methodology. A local projection model is used to estimate the cumulative changes in the share of informal output or informal employment over one to five years following a shift in financial development (annex 6A). Two dimensions of financial development that are particularly relevant for informal participants are examined. The first is the ability of individuals and companies to access financial services, which is proxied by the number of commercial bank branches per 100,000 adults. The second dimension, financial system depth, is proxied by domestic credit to the private sector in percent of GDP (Svirydzenka 2016; World Development Indicators 2020). The estimation controls for per capita GDP. The sample covers 125 EMDEs over 1990-2018.

Financial development in EMDEs. Measures to improve access to credit have been a common policy reform in East Asia and the Pacific (EAP), the Middle

BOX 6.1 Financial development and the informal economy (continued)

FIGURE B6.1.1 Financial development and informality in EMDEs

Firms and workers in EMDEs with more pervasive informality are more likely to be financially constrained, less likely to obtain bank finance, and more likely to have limited access to other financial services than those in EMDEs with less pervasive informality. As a result, firms in EMDEs with more pervasive informality rely more on internal financing.

A. Financial constraint facing firms and informality

B. Financing options facing firms

C. Access to finance and output informality (households)

D. Access to finance and employment informality (households)

Sources: International Monetary Fund (Financial Development Index Database); World Bank (Enterprise Surveys, Global Financial Development Database, World Development Indicators).

Note: Data are from emerging market and development economies (EMDEs) and the period 1990-2018. Output informality is measured by dynamic general equilibrium (DGE)-based estimates on informal output (in percent of official GDP). Employment informality is proxied by self-employment in percent of total employment. In A-D, *** denotes that the group differences are not zero at 10 percent significance level. "High informality" ("Low informality") are EMDEs with above-median (below-median) DGE-based informal output measure (or employment informality proxied by self-employment shares) over the period 2000-18 (2010-2018 in C-D).

A.B. Bars are simple group means using data from latest year available for EMDEs with "high informality" and those with "low informality." "Finance constrain" measures the percent of firms identifying access to finance as a major constraint in an economy. "Bank finance" measures the percent of firms using banks to finance investment in an economy. "Internal finance" measures the average share of investment financed internally using personal savings. C.D. Bars are unweighted averages of various financial development indicators for EMDEs with "high informality" and those with "low informality" over the period 2010-2018. Output informality is used in C and employment informality is used in D. "Bank branches" measures the number of commercial bank branches per 100,000 adults. "ATMs" measures the number of automated teller machines (ATMs) per 100,000 adults. "Private credit" measures domestic credit to private sector in percent of GDP. "FD index" is the financial development index from the IMF, which measures the overall level of financial development. "Account ownership" is the percentage of survey respondents (aged 15 or above) who report having an account (by themselves or together with someone else) at a bank or another type of financial institution or report personally using a mobile money service in the past 12 months. "Internal financing" is captured by the percentage of respondents (aged 15 or above) who report saving or setting aside any money in the past 12 months to start, operate, or expand a farm or business.

BOX 6.1 Financial development and the informal economy (continued)

East and North Africa (MNA), South Asia (SAR) and, more recently, Sub-Saharan Africa (SSA, chapter 5). Measures to expand access to finance have included better personal property registration to facilitate borrowing by informal firms (for example, Czech Republic; World Bank 2012) and digital payment systems to encourage a shift away from informal finance (World Bank 2017).

Overall, access to finance and the size of financial institutions increased in more than three-fifths of EMDEs over 2010-2018 (figure B6.1.2). The number of ATMs per 100,000 adults rose from 26 to 40, while the share of population with an account at a financial institution increased from 33 to 51 percent (Sviryzdenka 2016). Domestic credit to the private sector in EMDEs increased by more than 4 percentage points of GDP, on average, over the same period.

Changes in informality following financial development. Financial development was associated with significant contractions in both output and employment informality (figure B6.1.3; annex 6A). First, ten more bank branches per 10,000 adults—about the difference between the average EMDEs with above-median and below-median informality—were associated with a 0.1-0.3 percentage point decline in the share of informal output in the following 1 to 5 years. The share of informal employment also declined statistically significantly. Second, a 10-percentage-point-of-GDP increase in domestic credit to the private sector was associated with a significant contraction in the shares of output and employment informality in subsequent years.^e

Conclusion

Both theory and empirical evidence indicate that more advanced financial development is associated with a smaller informal economy, although the direction of causality remains a matter of debate and may run both ways. Financial development is considerably weaker in countries with more pervasive informality. Financial systems have deepened, and access to financial services has broadened, in EMDEs over the past three decades.

Policy measures to reduce informality, however, need to go beyond improving the financial system and facilitating access to credit. Evidence suggests that the impact of financial development on informality depends on the quality of the legal and regulatory systems, the level of economic development, and financial

e. The results remained broadly unchanged when levels of informal output and employment are used as robustness checks (see figure 6A.1 for results using levels of informal output). The robust results suggest that any movement in the informal share of output or employment is determined by changes in informal activity (the numerator), not by only changes in formal activity (the denominator).

C. Access to finance

D. Domestic credit to private sector

Sources: International Monetary Fund (Financial Development Index Database); World Bank (Global Financial Development Database, World Development Indicators).

Note: Data are from emerging market and development economies (EMDEs) and the period 1990-2018. Output informality is measured by dynamic general equilibrium-based estimates on informal output (in percent of official GDP). Employment informality is proxied by self-employment in percent of total employment.

A.B. Bars (A) and lines (B) show simple EMDEs averages for corresponding time periods. "Overall" is the aggregate financial development index obtained from the IMF. It measures the overall level of financial development and captures development in both "financial institutions" and "financial markets." The latter is about the access, depth, and efficiency of an economy's stock and debt market, which was less relevant for informal participants in EMDEs. The "Institutions" index measures how developed financial institutions are in terms of their depth (size and liquidity), access (ability of individuals and companies to access financial services), and efficiency (ability of institutions to provide financial services at low cost and with sustainable revenues). Some of the sub-indicators for "Institutions" are used in C-D to show the access (C) and depth (D) of financial institutions.

C. Bars show simple EMDE averages in earliest possible year (2004), 2010, and 2018. "Bank branches" measures the number of commercial bank branches per 100,000 adults. "ATMs" measures the number of automated teller machines (ATMs) per 100,000 adults. "Private credit" measures domestic credit to private sector in percent of GDP. "Account ownership" is the percentage of survey respondents (aged 15 or above) who report having an account (by themselves or together with someone else) at a bank or another type of financial institution or report personally using a mobile money service in the past 12 months. In the case of "account ownership," data from closest years are used.

D. Bars show simple EMDE averages in corresponding years. The indicators captures domestic credit to private sector as a share of GDP.

BOX 6.1 Financial development and the informal economy (continued)

FIGURE B6.1.3 Evolution of output informality following financial development in EMDEs

Financial development is found to have been associated with significant subsequent contractions in output informality. Financial development, especially better access to financial institutions and increased depth of financial institutions, helps reduce output informality.

A. Cumulative changes in output informality following a 10-unit increase in the number of bank branches per 100,000 adults

B. Cumulative changes in output informality following a 10-percentage-point-of-GDP increase in domestic credit to the private sector

Source: World Bank.

Note: Data are from emerging market and development economies (EMDEs) and the period 1990-2018. Output informality is measured by dynamic general equilibrium (DGE)-based estimates on informal output in percent of official GDP. The results are obtained via a local projection method where informality measures are detrended using Hodrick-Prescott (HP) filter. See annex 6A for detailed model specifications.

A,B. Bars show the cumulative changes in DGE-based output informality in percent of GDP following a 10-unit increase in the number of bank branches per 100,000 people (in A) and 10-percentage-point-of-GDP increase in the share of domestic credit to the private sector in percent of GDP (in B). Whiskers show the upper and lower bounds of the corresponding 90 percent confidence intervals. "t = n" shows cumulative changes over the n years after the policy change.

development itself. In addition, the effect of measures to promote financial development may be temporary and differ depending on the structure of financial markets.

In particular, improvements in the legal system may be a precondition for achieving broader access to credit that can draw informal firms into the formal sector. Measures to improve contract enforcement and investor protection may be particularly effective in EMDEs, which often fall well behind best practices.

Greater competition and access to markets may foster the productivity gains that are needed for firms to be able to service debt, one aspect of financial development. The possibility of reverse causality suggests that, in some instances, measures to reduce informality by streamlining regulations and improving their enforcement may create a virtuous circle of lowering informality and spurring financial development.

Second, the chapter describes novel empirical estimates of the cumulative changes in informality following various policy changes, obtained using a local projection model. Policy-related variables examined include tax rates, access to credit by the private sector, labor market efficiency, governance, and regulatory quality. This is the first study to conduct such empirical analysis for a wide range of policies. It is also the first to examine the share of informality in both economic output and employment: earlier studies have tended to focus on either informal output, or informal employment, or informal firms.⁴

Third, the chapter is the first published attempt to comprehensively examine the link between financial development and informality both theoretically and empirically (box 6.1). It reviews the literature identifying the channels through which limited financial development can discourage formalization. It uses both descriptive statistics and regression approaches to show that informality is associated with lack of financial development, and that improvements in access to finance are associated with declining informality.

Main findings. First, macroeconomic policies, governance and business climates have become more conducive to lowering informality over the past three decades. Over that period, EMDEs have reduced tax burdens, improved governance and regulatory quality, and expanded access to finance, education, and public services.

Second, policies that seek to streamline tax regulation, strengthen tax administration, and improve public service delivery have been associated with declines in informality. Separately, policies aimed at invigorating private sector activity broadly, such as measures to increase labor market flexibility, streamline regulatory frameworks for firm start-up, expand access to finance, and improve governance have also been associated with declines in informality.

Third, policy measures can have unintended consequences. For instance, trade liberalization that raised competition in the tradable sector was sometimes associated with greater informality in the short run, unless accompanied by measures that increase labor market flexibility. Also, reductions in informality have tended to be greater for reforms accompanied by business development and training programs, public awareness campaigns, and stronger enforcement.

Fourth, financial development has been associated with declining informality (box 6.1). It reduces the average costs of access to external financing and incentivizes firms to invest in higher-productivity projects and to join the formal sector. Over the past three decades, increased access to financial services and increased credit availability have been followed by declining informality.

Fifth, a comprehensive policy package tailored to country circumstances offers the greatest chance of success in reducing informality. A combination of measures to

⁴ See Bosch, Goñi-Pacchioni, and Maloney (2012); Fajnzylber, Maloney, Montes-Rojas (2011); Ihrig and Moe (2004); and Rocha, Ulyseas, and Rafter (2018).

strengthen economic development, boost productivity in both formal and informal sectors, streamline regulations and ensure effective enforcement can address multiple sources of informality. The relative priorities will depend on the economy-specific features of informality.

The rest of the chapter is organized as follows. It first presents a range of fiscal policy options that may be used to help remove barriers to joining the formal sector. It then discusses a wide range of policies that can ease the transition from the informal to the formal sector. The chapter also illustrates the importance of having a comprehensive and complementary policy package to tackle the challenges posed by informality and how to implement it successfully. In addition, the chapter describes the implications of digital technologies for coping with informality. The final section summarizes the conclusions.

Data and methodology

This chapter relies on the database developed in chapter 1 for measures of output and employment informality. It applies several statistical tests to quantify the linkages between a wide range of policies and informality, without establishing or assuming causality. It then estimates a series of local projection models to help quantify the cumulative response of informality to various policy actions over the short and medium terms.

Data. Both output and employment informality are considered here. Output informality is proxied by dynamic general equilibrium (DGE)-based estimates in percent of official GDP, and employment informality is proxied by self-employment in percent of total employment. Both measures are available for up to 121 EMDEs over the period 1990-2018.⁵ For the local projection estimation, all data series on informality are detrended using the Hodrick-Prescott filter to mitigate concerns that the results are driven by the declining trend in informality (chapter 2). A wide range of policy measures are considered here, ranging from changes in corporate tax rates to actions to improve the ease of doing business (table 6.2). Detailed data descriptions are provided in annex 6A.

Empirical strategy. The chapter applies two empirical approaches to assess the links between informality and policies.

First, differences between average policies in EMDEs with above-median and below-median informality are tested for statistical significance. The sample of EMDEs is grouped into those with an above-median share of informal output and those with a below-median share of informal output, on average during (up to) 1990-2018.⁶ For each

⁵In the case of financial development, absolute levels of informal output and informal employment, rather than their relative share of official GDP or total employment, are used as robustness checks when a local projection model is estimated (figure 6A.1). Using absolute levels of informal output and informal employment avoids the possibility that the results are driven by movements in total official GDP or total employment (the denominator) rather than movements in output or employment in the informal sector (the numerator).

⁶The results are the same when EMDEs are grouped according to employment informality (table 6.3).

subsample, simple averages of policy indicators are generated and the difference between these two group averages is tested for statistical significance. EMDEs with high informality refers to EMDEs with above-median informality, and EMDEs with low informality refers to EMDEs with below-median informality.

Second, a local projection model as in Jordà (2005), Teulings and Zubanov (2014), and World Bank (2018c) is estimated to identify the effects of policy changes on informality over time for a sample of up to 125 EMDEs during 1990-2018. The model estimates the cumulative changes in informality after policy changes over different time horizons while controlling for country fixed effects and per capita income levels (table 6.4).⁷ Policy changes are defined as a unit change in the corresponding policy indicator. For instance, a 1-percentage point increase in the personal income tax rate is considered as a tax policy change. Annex 6A details the model specification.

Fiscal measures

High tax rates or payments, complicated tax codes, and administrative burdens have been commonly cited as reasons for informal activity (Auriol and Warlters 2005; Perry et al. 2007; Waseem 2018). Lax tax enforcement facilitates poor tax compliance (Slemrod 2019). Poor government services—often underfunded and inefficiently delivered—will tend to erode tax morale (Awasthi and Engelschalk 2018). In a sweeping survey of the literature, measures to address such issues have been identified as having been particularly effective at encouraging a shift into formal activity (Jessen and Kluge 2021; World Bank 2019b).

Tax rates

Higher tax rates in more informal EMDEs. On average during 2010-2018, average corporate and personal incomes tax rates were significantly higher, by 3 (corporate) to 4 (personal) percentage points in EMDEs with above-median output informality than in those with below-median output informality. VAT rates were also statistically significantly higher in EMDEs with above-median output informality than in those with below-median output informality.⁸

Over time, shift away from income taxes. Since 1990, both corporate and personal income tax rates have been lowered in EMDEs while the use of value-added tax (VAT) has expanded. Average corporate and personal income tax rates in EMDEs have fallen by 13 and 15 percentage points, respectively, from close to 40 percent in the beginning of

⁷The results are robust to using self-employment as a measure of employment informality (table 6.5). As further robustness checks, both ordinary least squares and quantile regressions are performed using the same set of policy for both output and employment informality measures. The regression results are largely in line with the findings from the group comparison approach (tables 6.6-6.7).

⁸In contrast, EMDEs with high or low informality often do not differ significantly in their average statutory rates for social security contributions nor their revenue collections from such taxes, but they do differ significantly in the amount of social security they provide (see below).

1990s to about 24 percent in 2020 (figure 6.2). Around two-thirds of EMDEs lowered their statutory personal income tax rates and more than three-quarters lowered their statutory corporate income tax rates over the sample period.⁹ These efforts often coincided with a streamlining of tax regulations and a broadening of the tax base (Kopczuk 2005).

While income tax rates were lowered, often to reduce distortions that discourage employment, value added taxes (VAT) were introduced, which could be less distortionary than income tax but may lead to a more regressive tax system (Cnossen 1998).¹⁰ Many economies in Latin America introduced VAT regimes in the 1970s and 1980s, and their ranks were joined by a large number of economies in Europe and Central Asia (ECA) during the 1990s. Between 1990 and 2020, the number of EMDEs with VAT systems increased from 29 to 91 (Végh and Vuletin 2015; World Bank 2020a).

Lower informality after tax rate cuts. Lower corporate or personal income tax rates can reduce the incentives of firms and households to operate in the informal economy to lower their costs. In one EMDE, for example, a tax hike in 2010 reduced the number of formal firms and their sales revenues, to such an extent that tax revenues three years after the hike were lower than they would have been without the tax hike (Waseem 2018). A sweeping review of past government interventions suggests that tax cuts were particularly effective in reducing informality (Jessen and Kluge 2021). Similarly, a review of policies showed that tax simplification and tax cuts were associated with lower informality (World Bank 2019b).

Meanwhile, the introduction of VAT may strengthen incentives to register in order to qualify for VAT refunds—or, conversely, may strengthen incentives to operate informally to offer lower prices excluding VAT. A VAT regime imposes an input tax on informal firms that do not qualify for refunds but source from formal firms, which in the right circumstance can motivate them to register, thus raising government revenue collection (de Paula and Scheinkman 2010; Loayza 2018; World Bank 2018b).¹¹ A requirement to digitalize sales receipts for accelerated VAT refunds could further strengthen incentives to register and correctly report sales (Fan et al. 2020). In one case, electronic invoicing for VAT purposes was rolled out in waves between 2014 and 2018 and resulted in more than 5 percent higher reported firm sales, purchases and value-added in the first year after adoption (Bellon et al. 2019).

Indeed, since 1990, a 10-percentage-point decrease in the corporate income tax rate has been associated with a cumulative decline in output informality of about 0.1 percentage

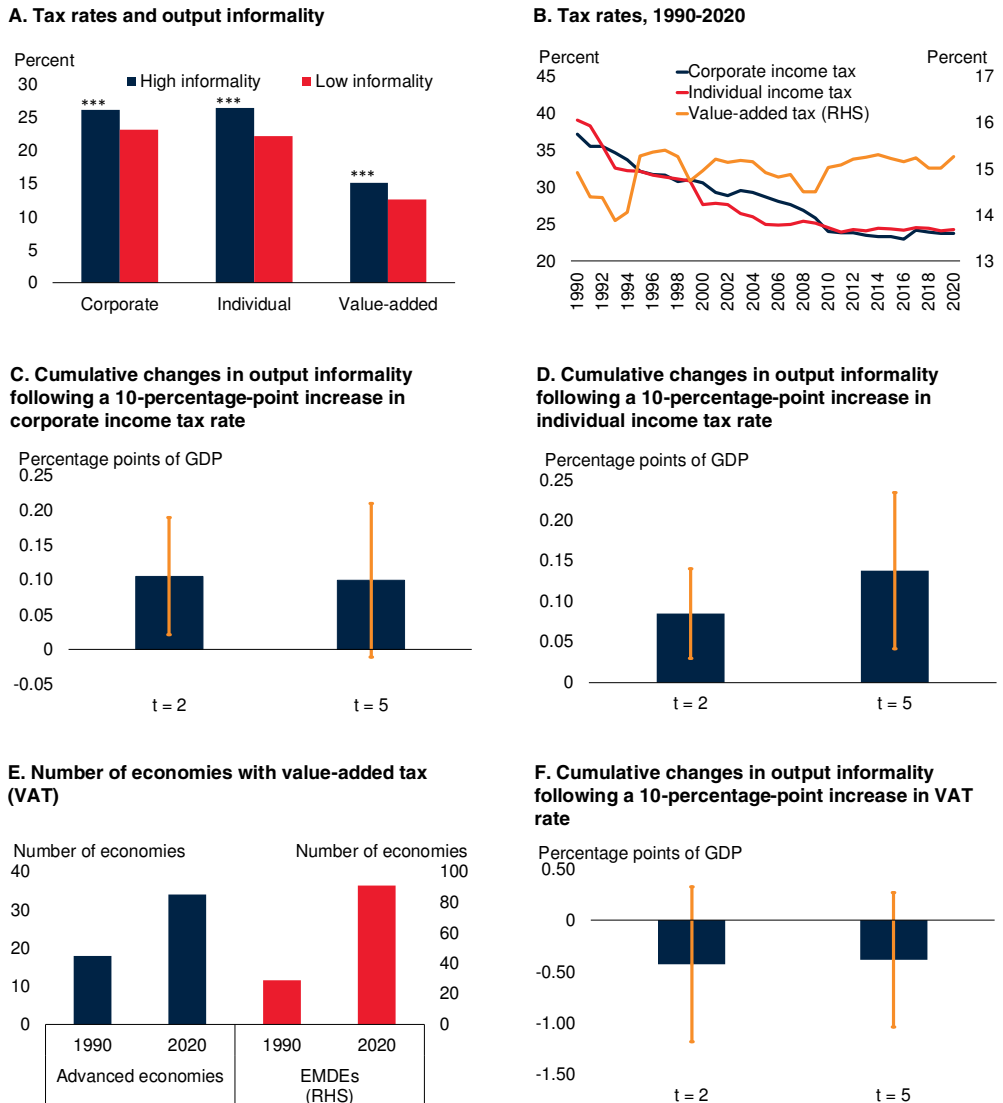

⁹The sample contains up to 53 EMDEs where data are available in 2020 and 1990.

¹⁰That said, the presence of an informal economy could lead to incomplete coverage and inefficiencies in the VAT system (Keen 2008; Piggott and Whalley 2001; Shahe, Emran and Stiglitz 2005). In some case, labor informality was found to be associated with lower overall VAT collection (Caro and Sacchi 2021).

¹¹Poorer households tend to spend a larger share of their budgets in the informal sector than richer households. As a result, households in the richest quintile can face an effective consumption tax rate that is twice that of the poorest quintile (Bachas, Gadenne, and Jensen 2020).

FIGURE 6.2 Tax rates and informality in EMDEs

Income tax rates remain higher in EMDEs with more pervasive informality—even where governments have cut rates and shifted towards value-added taxation. Informality declined after income tax rate reductions but not after value-added tax (VAT) rate reductions.

Sources: Cnossen (1998); KPMG; University of Michigan; Organisation for Economic Co-operation and Development; Végh and Vuletin (2015); World Bank (*Doing Business*).

Note: EMDEs = emerging market and developing economies.

A. *** denotes that the group differences are not zero at 10 percent significance. Bars are group means for EMDEs with above-median dynamic general equilibrium (DGE)-based estimates on informal output (“high informality”) or those with below-median DGE-bases estimates on informal output (“low informality”) over the period 2010-2018. Data are from about 100 EMDEs (in the case of individual tax rate, China is dropped as an outlier). Bolivia, Georgia, Panama, and Zimbabwe are dropped as outliers.

B. Lines are simple group averages for EMDEs.

C.-D., F. Bars show the cumulative changes in DGE-based output informality in percent of GDP following 10-percentage-point increase in corporate income tax rate (C), individual income tax rate (D), and value-added tax rate (F). Whiskers show the upper and lower bounds of the corresponding 90 percent confidence intervals. “t = n” indicates the cumulative changes in output informality over the n years after a policy change. Data are for EMDEs over the period 2010-2018. See annex 6A for detailed model specifications.

E. Bars show the number of EMDEs and advanced economies that adopted a value-added tax.

point of GDP, relative to trend, over the following two years (figure 6.2). A similarly-sized reduction in the personal income tax rate has been associated with a slightly stronger, and deepening, fall in output informality in the following five years. Despite finding significant falls in informality following tax cuts, these falls are generally small in size, suggesting that cutting tax rates alone is not enough to move all participants from the formal sector to the informal sector. Other policy measures are needed (Loayza 2018). Meanwhile, increases in VAT have not been associated with any significant change in output informality. This suggests that some informal firms source their inputs from informal markets that operate outside the VAT system. The results are robust to using employment informality, instead of output informality.

Tax compliance

More burdensome tax compliance in more informal EMDEs. Beyond tax rates, tax compliance can be costly and time-consuming and, thus, discourage formal registration by firms, especially those with poor profitability (Morales and Medina 2016; Rocha, Ulyseas, and Rachter 2018; Ulyseas 2018). In the average EMDE with above-median informality during 2010-18, it took the average firm 33 hours longer and required statistically significantly more payments, estimated at 11 per year, to comply with tax regulations than in the average EMDE with below-median informality (figure 6.3). As a result, despite higher corporate and personal income tax rates in EMDEs with above-median informality, revenue collections were lower: In the average EMDE with above-median output informality, personal and corporate income tax revenues were statistically significantly lower, by 0.6 and 0.8 percentage point of GDP, than in the average EMDE with below-median informality.

Similar administrative challenges have troubled the administration of VAT regimes in countries with high informality. During 2016-18, firms spent 29 hours a year, on average, on complying with VAT refund requirements in EMDEs with above-median informality—7 hours more than in EMDEs with below-median informality, though the difference is not statistically significant.¹² It took about 40 weeks for firms in EMDEs with above-median informality to receive VAT refunds—significantly longer than the 31 weeks in EMDEs with below-median informality.

Over time, less burdensome tax compliance. Firms' tax compliance costs have declined in EMDEs in the past few decades. Since 2006, the time spent by firms on paying taxes has fallen by 68 hours a year in the average EMDE and the average number of tax payments per year has declined by one-third, to 26 payments per year in 2020 (figure 6.3). In ECA, the introduction of electronic tax filing and payment systems has reduced the average tax filing time from 473 hours in 2006 to 225 hours in 2020 (World Bank and PwC 2019).

¹² In the case of employment informality, the average annual number of hours spent on complying with VAT refund requirements amounted to 37 in EMDEs with above-median informality—20 hours per year significantly more than in EMDEs with below-median informality (table 6.3).

FIGURE 6.3 Firms' tax compliance burdens and informality in EMDEs

Tax compliance burdens on firms remain higher in emerging market and developing economies (EMDEs) with more pervasive informality than in those with less pervasive informality, despite recent declines. Past efforts to lower compliance costs were not followed by immediate declines in informality.

A. Ease of paying taxes and output informality

B. Ease of paying taxes over time

C. Time to comply with and obtain VAT refund and output informality

D. Cumulative changes in output informality following a 1-point increase in the score for ease of paying taxes

Sources: World Bank (*Doing Business*).

A.C. *** denotes that the group differences are not zero at 10 percent significance. Bars are group means using data from latest year available for emerging market and developing economies (EMDEs) with "high informality" and those with "low informality." "High informality" ("low informality") are EMDEs with above-median (below-median) dynamic general equilibrium (DGE) model-based informal output measure over the period 2010-2018. Data are from about 100 EMDEs.

B. Bars show the average number of tax payments per year by a medium-size company, while the line shows the average time spent on paying taxes per year by a medium-size company. Data are for EMDEs.

D. Bars show the cumulative changes in DGE-based output informality in percent of GDP following a 1-point increase in the score for ease of paying taxes. Whiskers show the upper and lower bounds of the corresponding 90 percent confidence intervals. "t = n" indicates the cumulative changes in output informality over the n years after a policy change. Data are for EMDEs over the period 1990-2018. See annex 6A for detailed model specifications.

Efforts to lower tax burdens have been among the most common policy reforms in EMDEs, especially in East Asia and Pacific (EAP) and Latin America and Caribbean (LAC). Measures to make tax compliance less burdensome have ranged widely (Awasthi and Engelschalk 2018; Slemrod 2019). Tax bases have been simplified in industries with a high percentage of undeclared workers (for example, domestic work) and tax regulations have been harmonized across different types of firms (Oviedo, Thomas, and Karakurum-Özdemir 2009). At the same time, tax enforcement has been stepped up by expanding the use of information technology and communication tools, encouraging a

switch from cash-based transactions to bank-based ones, and strengthening the capacity of tax administrations (for example, Nguimkeu and Okou 2019; Prichard et al. 2019).¹³

Lower informality after measures to facilitate tax compliance. Measures to reduce the burden of tax compliance or firm registration can lower the cost for informal firms of moving into the formal sector (Rocha, Ulyssea, and Rochater 2018). Coordination of minimum tax thresholds across different types of tax, such as personal income tax, VAT, and social security contributions, could increase tax compliance and improve welfare (Kanbur and Keen 2014). Measures to harmonize tax provisions or other regulations across different types of firms can reduce incentives for firms to evade taxation and remain small and informal (Harju, Matikka and Rouhanen 2019; Dabla-Norris, Gradstein, and Inchauste 2018). Measures to strengthen tax administration can increase the likelihood of detection of informal firms that do not comply with taxes (Carrillo, Pomeranz, and Singhal 2017; Naritomi 2019).

Measures to facilitate tax compliance have been accompanied by statistically significant declines in output informality (figure 6.3). The effects have not been immediate, being insignificant in the first year, but have strengthened over time. Thus four years after reforms that increased the score for the ease of paying taxes by one point, the share of output informality was 0.1 percentage point of GDP lower—a statistically significant difference.

Tax morale

Weaker tax morale in more informal economies. Tax morale is weaker in EMDEs with above-median informality. In the average EMDE with above-median output informality, the average household scores 2.5 points on a scale of 0-10, with 10 indicating that underreporting of income for tax purposes is always justifiable—0.4 index points, and statistically significantly, higher than in the average EMDE with below-median informality (figure 6.4).

Among the many reasons for weaker tax morale is a lack of trust in the government or dissatisfaction with the quality of public service delivery.¹⁴ Indeed, entrepreneurs in EMDEs with above-median output informality report significantly poorer access to government support and programs as well as poorer physical and services infrastructure than entrepreneurs in EMDEs with below-median output informality (figure 6.4; chapter 4). Similarly, significantly better access to commercial and professional infrastructure is reported by businesses in EMDEs with above-median tax morale than those in EMDEs with below-median tax morale. Coverage of unemployment benefits is significantly lower, by about 3 percentage points of the population, in EMDEs with

¹³ See Chodorow-Reich et al. (2018); Crouzet, Gupta, and Mezzanotti (2020); and Lahiri (2020) for the impact of demonetization.

¹⁴ See Daude, Gutiérrez, and Mulguzo (2012) for a review of drivers of tax morale. OECD (2019) suggested that there is a positive association between tax morale and public service provision in Africa, while tax morale in Latin America is more linked with trust in the government.

FIGURE 6.4 Tax morale and informality in EMDEs

Tax morale is higher in EMDEs with lower informality. Higher tax morale has been associated with better government services such as social security, infrastructure, education, and health care systems.

A. Tax morale and informality

B. Government support and informality

C. Tax morale and access to government services

D. Adequacy of social security and informality

E. Access to infrastructure and informality

F. Health and education outcomes and informality

Sources: Global Entrepreneurship Monitor; Programme for International Student Assessment (PISA) database; World Bank (World Development Indicators).

Note: Data are from emerging market and development economies (EMDEs) and the period 1990-2018. "High (Low) informality" are EMDEs with above (below)-median output informality (proxied by dynamic general equilibrium-based estimates on informal output in percent of GDP). All scores on government support and public infrastructure in B and C are for the period 2000-18 and range from 1 (worst) to 4 (best). *** denotes that the group differences are not zero at 10 percent significance.

A. Bars show simple group averages between 1990 and 2018. World Value Survey (WVS) asks whether cheating on taxes is justifiable, with a higher level suggesting that the economy is more tolerant towards the informal sector.

B.C. Bars show simple group averages. "Governmental support and policies" measures the extent to which policies support entrepreneurship as a relevant economic issue. "Government programs" captures the presence and quality of programs directly assisting small and medium-sized enterprises (SMEs) at all levels of government (national, regional, municipal). "Commercial and professional infrastructure" captures the presence of property rights, commercial, accounting, and other legal and assessment services and institutions that support or promote SMEs. "Physical and service infrastructure" measures the ease of access to physical resources at a price that does not discriminate against SMEs.

D. Adequacy of social insurance programs is measured as total transfer amount received by population participating in social insurance programs in percent of total income or expenditures of beneficiary households.

E. Bars show simple group averages.

F. PISA testing scores are for students aged 15.

above-median informality than in those with below-median informality. In an average EMDE with below-median informality, social insurance programs can cover about 34 percent of the annual income or consumption of the beneficiary household, which is significantly lower, by 6 percentage points, than in EMDEs with above-median informality.

Education and health outcomes are significantly poorer in EMDEs with above-median informality, with Programme for International Student Assessment (PISA) test scores for 15-year-old students in EMDEs with above-median informality being lower by about 10 percent than in those with below-median informality, and life expectancy eight years lower in EMDEs with above-median informality. The poorer outcomes are partly due to more limited government expenditures on education and health in EMDEs with more pervasive informality (chapter 4).

Over time, stable tax morale, despite better government services. In contrast to output and employment informality, tax morale has remained stable over the past three decades. In the early 1990s, the average household in EMDEs gave a score of 2.5 to the justifiability of cheating on taxes (where a score of 1 means that cheating on taxes is never justifiable and 10 means that it is always justifiable)—virtually the same as in 2010.¹⁵ As one of the social capital measures with deep roots in culture, tax morale is slow-moving by nature (Luttmer and Singhal 2014). In contrast, entrepreneurs in the average EMDE have perceived statistically significant improvements in government support or programs for small and medium-sized enterprises (SMEs) and in improving commercial and professional infrastructure available to SMEs (figure 6.5).

Meanwhile, actual government service delivery has improved by several measures. The adequacy of social insurance programs has risen in the average EMDE from 31 percent of household income in the 2000s to 34 percent a decade later. Infrastructure—for example, road kilometers, access to reliable power, and access to internet services—has improved considerably since 2000. Mobile cellular subscriptions rose from 28 to 95 per 100 people between the 2000s and the 2010s. EMDEs' test scores on PISA indicators of education outcomes have risen significantly, by 17 points, and life expectancy has risen by 4 years in the average EMDE.

A range of measures have been introduced over the past three decades to cultivate better tax morale, including public appeals to declare activities, campaigns to encourage a culture of commitment to declaration, and efforts to change perceptions of the tax system's fairness (Williams and Schneider 2016). Other measures have included steps to shift the burden of payments of social security contributions from employers to employees (for example, in Latvia, Poland, Slovenia), to reduce employers' social security contributions (for example, in Bulgaria), and to link social benefits to personal

¹⁵The indicator for tax morale is taken from World Value Surveys (WVS), conducted in various years. The current round of WVS will complete its data collection in December 2021.

FIGURE 6.5 Government services in EMDEs, 2000-18

Although infrastructure, social security systems, and health care systems have improved in EMDEs over the past several decades, entrepreneurs' perceptions of the adequacy of government services have remained stable and poor.

A. Government support perceived by entrepreneurs

B. Social security

C. Public infrastructure

D. Health and education outcomes

Sources: Global Entrepreneurship Monitor; Programme for International Student Assessment (PISA) database; World Bank (World Development Indicators).

Note: Data are from emerging market and development economies (EMDEs) and the period 2000-2018. All scores on government support and public infrastructure in A are taken from the National Expert Survey of the Global Entrepreneurship Monitor for the period 2000-2018. The scores range from 1 to 4 with a lower score representing poorer entrepreneurial conditions. Bars show simple period averages for 2000-08 and 2010-2018, correspondingly, with *** indicating that the period differences are not zero at 10 percent significance level.

A. "Government support and policies" measures the extent to which policies support entrepreneurship as a relevant economic issue. "Government programs" captures the presence and quality of programs directly assisting small and medium-sized enterprises (SMEs) at all levels of government (national, regional, municipal). "Commercial and professional infrastructure" captures the presence of property rights, commercial, accounting, and other legal and assessment services and institutions that support or promote SMEs. "Physical and service infrastructure" measures the ease of access to physical resources—communication, utilities, transportation, land, or space—at a price that does not discriminate against SMEs.

B. Adequacy of social insurance programs are measured in percent of total welfare of beneficiary households.

C-D. PISA scores are for students aged 15. "Paved road" is calculated as 100 minus the share of unpaved road in percent of total road. "Access to electricity" and "Internet users" are in percent of population, while "mobile cellular subscriptions" and "fixed broadband subscriptions" are measured as per 100 people.

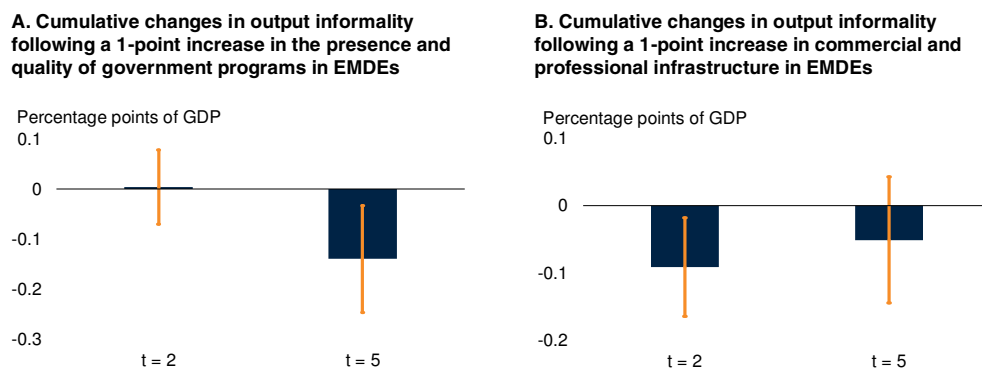

contributions (for example, in most EU 27 economies; Oviedo, Thomas, and Karakurum-Özdemir 2009).¹⁶

Lower informality after improvements in government services. Improvements in the perception that tax dollars are spent judiciously—that is, for appropriate objectives and

¹⁶Transitions from an employment-based social security system to a well-designed model of risk sharing can further improve the safety net for informal workers and help protect both formal and informal workers during economic downturns (World Bank 2013, 2018a).

FIGURE 6.6 Informality after improvements in government services

After improvements in government services, informality has declined.

Source: World Bank.

Note: Data are from emerging market and development economies (EMDEs) and the period 2000-2018. Both scores taken from National Expert Survey of the Global Entrepreneurship Monitor for the period 2000-18. The scores range from 1 (worst) to 4 (best).

A.B. Bars show the cumulative response of dynamic general equilibrium (DGE)-based output informality in percent of GDP to a 1-point increase in “government programs” index (A) and “commercial and professional infrastructure” (B). Whiskers show the upper and lower bounds of the corresponding 90 percent confidence intervals. The results are obtained via a local projection method. Output informality in percent of GDP is detrended using Hodrick-Prescott (HP) filter. “t = n” indicates the cumulative changes over the n years after a policy change. See annex 6A for detailed model specifications.

in an efficient way—can encourage greater tax compliance and lessen informality (Sung, Awasthi, and Lee 2017). Better education or infrastructure can help raise labor productivity in both formal and informal activities, thus facilitating a move of previously insufficiently productive, informal firms into the formal sector.¹⁷

Empirically, declines in output informality followed improvements in government services, although the small country sample of data for tax morale blunts the significance of coefficient estimates (figure 6.6). Measures perceived to improve government support for SMEs by 1 standard deviation were followed by a 0.1 percentage point decline in the share of output informality five years later. A similar, 1-standard-deviation improvement in SMEs’ access to quality commercial and professional infrastructure was also followed by an 0.1 percentage point decline in the informal output share after two years, although the effect subsequently dissipated.

Other policies

Many reforms designed to invigorate private sector growth can also help lower informality, such as reducing corruption, improving business climates and governance,

¹⁷ See, for instance, Benjamin and Mbaye (2012); Kim, Loayza, and Meza-Cuadra (2016); Oviedo, Thomas, and Karakurum-Özdemir (2009); and World Bank (2018b). Better access to education or infrastructure may boost productivity growth more in the formal sector than in the informal sector, resulting in a fall in the relative share of informal output in total economic output.

strengthening enforcement of taxes and regulations, and liberalizing labor and product markets, including through trade liberalization.¹⁸ Financial development, by lowering financing costs, can incentivize firms to operate formally, and has often been associated with a shrinking informal sector (box 6.1). Policy measures that narrow the earnings gap between informal and formal workers or reduce the labor productivity gap between informal and formal firms, such as measures that improve access to education or training programs, can also help reduce informal activity.

Labor market regulations

More restrictive regulations in more informal economies. While higher minimum wages may attract informal workers into the formal sector, they are also likely to discourage firms from hiring workers, resulting in unclear effects on employment of minimum wages (especially in the presence of imperfect competition).¹⁹ In a development context, in which agricultural sectors are large and urbanization is still underway, a higher minimum wage can slow capital accumulation and push workers into informal employment (Loayza 2016).

Empirically, labor market regulations in EMDEs with above-median informality are more restrictive than in EMDEs with below-median informality (figure 6.7). Minimum wages in EMDEs with above-median output informality average 5.5 percent of per capita income, which is 1.3 percentage points, and significantly, higher than in EMDEs with below-median output informality. Flexibility of working hours, often measured by the inverse of restrictions on night and overtime work, holiday work, and the length of the work week, is significantly less in EMDEs with above-median output informality than in EMDEs with below-median output informality.

Over time, increased labor market flexibility. Labor market flexibility and efficiency have increased in EMDEs over the past three decades (figure 6.7). EMDEs have lowered their minimum wage by 0.6 percentage points of GDP per capita from its level in the 1990s (Loayza 2016). Between 2010 and 2018 alone, about one-quarter of EMDEs increased their perceived labor market efficiency, which measures the extent to which the labor market matches workers with the most suitable jobs for their skillset (WEF 2020). About 40 percent of EMDEs changed regulations to make the hiring and dismissal of workers more flexibly determined by employers. During the same period, four out of ten EMDEs reduced the costs of advance notice requirements, severance payments, and the penalties due when dismissing a worker with a ten-year tenure.

¹⁸ Kuddo (2018) shows that about 60 percent of the reforms implemented between 2007 and 2017 throughout the world aimed at improving labor market flexibility. Among measures to improve product market flexibility, trade liberalization has been associated with increased informality unless complementary reforms improved labor market flexibility (World Bank 2019b).

¹⁹ The employment effects of minimum wages have been unclear (Manning 2021). An increase in the real minimum wage has been associated with a lower probability of being hired in the formal sector, or employment in general (Gindling and Terrell 2007; Maloney and Nuñez Mendez 2004). However, employment effect was not found in studies like Hohberg and Lay (2015); Lemos (2009); and Urzua and Saltiel (forthcoming).

FIGURE 6.7 Labor market reforms and informality in EMDEs

Labor market regulations are more restrictive in EMDEs with high informality than in those with low informality. About one-third of EMDEs have improved their labor market efficiency and eased labor market regulations over the past several decades.

A. Labor market regulations and output informality

B. Minimum wage and output informality

C. Specific labor market regulations and output informality

D. EMDEs with liberalized labor market regulations between 2010 and 2018

Sources: Fraser Institute; International Labour Organization (ILO); World Economic Forum (WEF).

Note: The labor market regulation index from the Fraser Institute covers issues such as minimum wage, hiring and firing regulations, centralized collective bargaining, mandated cost of hiring, mandated cost of worker dismissal, regulation of hours, and conscription. A.-C. *** denotes that the group differences are not zero at 10 percent significance. Bars are group means using data available between 1990 and 2018 for emerging market developing economies (EMDEs) with "high informality" and those with "low informality." "High informality" ("Low informality") are EMDEs with above-median (below-median) dynamic general equilibrium (DGE)-based informal output measure over the period 1990-2018. In B, data are between 1994 and 2018. Data on labor market regulations are obtained from the Fraser Institute (in A and C) and are between 1990 and 2018. The WEF index is available between 2007 and 2017. The labor market efficiency index from WEF measures the extent to which the labor market matches workers with the most suitable jobs for their skillset (1 = worst; 7 = best). The labor market regulation index from the Fraser Institute measures the extent to which these restraints (listed in C) upon economic freedom are present in the labor market (1 = worst; 10 = best). D. Bars show the share of EMDEs with improved labor market regulations between 2010 and 2018. "Labor market eff. index" is the labor market efficiency index obtained from WEF.

These changes reflect several decades of labor market reforms especially in ECA, SSA and, more recently, LAC. Regulations with respect to hiring and dismissal, working hours, and wage rates have been eased in ECA (EBRD 2018). Incentives have been provided for worker registration—for example, legalization of undocumented workers—while enforcement of existing labor laws has been tightened (Anand and Khera 2016; Munkacsi and Saxegaard 2017). In EMDEs, the reduction of minimum wages encouraged formalization of employment (Betcherman, Meltem Daysal, and Pagés 2010; Kugler, Kugler, and Herrera-Prada 2017).

FIGURE 6.8 Informality after labor market reforms in EMDEs

Efforts to increase labor market flexibility and efficiency have been followed by declines in output informality.

A. Cumulative changes in output informality following a 1-point increase in Fraser Institute index of hiring and firing regulations in EMDEs

B. Cumulative response of output informality to a 1-point increase in WEF index of labor market efficiency in EMDEs

Source: World Bank.

Note: The labor market efficiency index from World Economic Forum (WEF) measures the extent to which the labor market matches workers with the most suitable jobs for their skillset (1 = worst; 7 = best). The index on hiring and firing regulations is from the Fraser Institute, which measures the extent to which hiring and firing regulation are restricting economic freedom in the labor market (1 = worst; 10 = best). Data are for emerging market and developing economies (EMDEs) over the period 1990-2018.

A.B. Bars show the cumulative changes in dynamic general equilibrium (DGE)-based output informality in percent of GDP to a 1-point increase in the Fraser Institute's index on hiring and firing regulations (1-point increase in WEF labor market efficiency index in B). Whiskers show the upper and lower bounds of the corresponding 90 percent confidence intervals. The results are obtained via a local projection method. Output informality in percent of GDP is detrended using Hodrick-Prescott (HP) filter. "t = n" indicates the cumulative changes in output informality over the n years after a policy change. See annex 6A for detailed model specifications.

Lower informality after labor market reforms. Excessive labor market regulations, such as excessively high minimum wages, can distort the labor market and provide incentives for firms to hire workers informally (Kugler 2004; Loayza 2016; Ulyssea 2010). Increases in labor market flexibility and efficiency have been associated with significant falls in output informality (figure 6.8). A 1-standard-deviation increase in the Fraser Institute's index of hiring and firing regulation, which gauges the extent to which the hiring and dismissal of workers is at the employer's discretion, was associated with a significant drop in output informality, by 0.5 percentage points, over the following five years. A 1-point increase in the World Economic Forum's labor market efficiency index was associated with a cumulative drop in output informality by about 0.2 percentage points of GDP over the following five years.²⁰

Firm start-up costs

More difficult firm start-up in more informal economies. Starting a new firm is more challenging in EMDEs with more pervasive informality (figure 6.9). On average, the costs of business start-up amount to about 90 percent of per capita gross national income (GNI) in EMDEs with above-median output informality—three times the level

²⁰ A similarly sized increase in labor market efficiency was associated with a decline in employment informality by 2 percentage points of employment, cumulatively, over the following 2-3 years.

FIGURE 6.9 Firm start-up cost and informality in EMDEs

Firm start-ups are more challenging in EMDEs with above-median informality than in those with below-median informality. Over the past two decades, EMDEs have taken measures to facilitate firm start-up. Reduced start-up costs have been followed by significant contractions in informal output.

Source: World Bank (*Doing Business*).

Note: Data are from emerging market and development economies (EMDEs) and the period 1990-2018.

A. The bars show unweighted group averages. "High-informality" ("Low-informality") are EMDEs with above-median (below-median) dynamic general equilibrium (DGE)-based informal output measures. *** denotes that the group differences between EMDEs with above median informality and those with below-median informality are significant at 10 percent level. The data are from 2003-2018. B. Lines show unweighted averages for EMDEs for the period 2003-2018.

C, D. Bars show the cumulative changes in DGE-based output informality in percent of GDP following a 10-percentage-point-of-GNI-per-capita decrease in the cost of business start-up procedures (C); or following a 1-unit increase in the number of days required to start a business in D). Whiskers show the upper and lower bounds of the corresponding 90 percent confidence intervals. "t = n" indicates the cumulative changes in output informality over the n years after a policy change. See annex 6A for detailed model specifications.

in other EMDEs. It takes 33 days to start a business in EMDEs with above-median informality—about 1 day longer than in other EMDEs, although the difference is not statistically significant.

Over time, easier firm start-up. Business start-up costs have fallen steadily in EMDEs over the past two decades. Between 2003 and 2018, the costs of business start-up fell from above 130 percent of per capita GNI to below 30 percent, and the number of days required to start a business declined by two-thirds, to 23 days. There has also been a reduction in the number of procedures needed to start a business (World Bank 2020a).

A variety of regulations have been used to encourage formal firm start-up. “One-stop-shop” registrations have been created (for example, in Ukraine) to simplify the firm start-up process. Similar reforms have been carried out in several other EMDEs (World Bank 2009, 2010, 2011). EMDEs in ECA and SSA have implemented an above-average number of reforms to reduce the costs of starting a business during the past decade.

Lower informality after regulatory easing. Easier and less costly firm registration reduces the costs for firms of entering the formal sector (Haltiwanger, Jarmin, and Miranda 2013; Nguimkeu 2015; Loayza 2018). Empirically, a reduction in the costs of business start-up by 10 percentage points of GNI per capita was associated with a significant reduction in output informality, by 0.1 percentage point of GDP over the following five years. Similarly, a 1-day reduction in the number of days required to start a business was associated with a significant contraction in output informality, by 0.4 percent point of GDP over the following two years.

Governance

Weaker governance in more informal economies. More corruption, less effective government, and weaker law and order have been associated with larger informal sectors in EMDEs (figure 6.10; chapter 4). On average in the past three decades, EMDEs with above-median output informality scored significantly lower (by about half of a standard deviation) on government effectiveness, control of corruption, and rule of law than other EMDEs. Using the ICRG indicators, bureaucracy quality, control of corruption, and law and order in EMDEs with above-median output informality are significantly lower, by 0.4-0.7 standard deviation, than in EMDEs with below-median informality.

Over time, improved governance. Governance has generally improved in EMDEs since 1990. Both bureaucracy quality and law and order improved by 0.2-0.6 standard deviation between 1990 and 2018. Control of corruption, law and order, and bureaucracy quality strengthened in the early 1990s but weakened again in the second half of the 1990s with the economic, social, and political disruptions in transition economies, before stabilizing in the early 2000s.

To improve governance and regulatory quality, countries have increased the frequency of inspections (for example, in most EU15 economies and Bangladesh), created a national-level firm or employee registry (Poland), and launched public awareness campaigns regarding tax compliance (for example, China, Republic of Korea).²¹ Such measures have been most effective in reducing informality when implemented in conjunction with steps to improve labor market functioning and when applied evenhandedly to both formal and informal firms (Loayza 2018). In Georgia, during 1996-2016, the transition to a market economy brought significant improvements in government effectiveness, control of corruption, and law and order (World Bank

²¹ See, for instance, Awasthi and Engelschalk (2018); Bruhn and McKenzie (2014); De Giorgi, Ploenzke, and Rahman (2018); and Oviedo, Thomas, and Karakurum-Özdemir (2009).

FIGURE 6.10 Governance and informality in EMDEs

Governance and regulatory quality tend to be weaker in EMDEs with more pervasive informality but have improved over the past several decades. Such improvement has often been followed by declines in informality.

A. Governance and informality: ICRG indicators

B. Governance in EMDEs, 1990-2018

C. Perceived level of corruption in EMDEs, 2012-20

D. Cumulative change in output informality following a 1-point improvement in control of corruption (ICRG)

Sources: Transparency International - Corruption Perceptions Index (dataset); *International Country Risk Guide (ICRG)* dataset; World Bank.

Note: Data are from emerging market and development economies (EMDEs) and the period 1990-2018.

A. The bars show the unweighted group averages. "High (Low)-informality" are EMDEs with above-median (below-median) dynamic general equilibrium (DGE)-based informal output measures. *** denotes that the group differences are significant at 10 percent level.

B. Lines show simple averages for EMDEs using various indicators from ICRG. A higher value indicates better governance.

C. Bars show the unweighted averages of the perceived level of corruption in EMDEs. The measure ranges from 0 (the highest level of perceived corruption) and 100 (the least level of perceived corruption).

D. Bars show the cumulative changes in DGE-based estimates on output informality to a 1-point increase in control of corruption. Whiskers show the upper and lower bounds of the corresponding 90 percent confidence intervals. "t = n" indicates the cumulative changes in output informality over the n years after a policy change. The results are obtained via a local projection method. Output informality in percent of GDP is detrended using Hodrick-Prescott (HP) filter. See annex 6A for detailed model specifications.

2019b).²² With output growth averaging about 6 percent per year, the share of informal output fell by 9 percentage points of GDP, and the share of informal employment in total employment fell by a similar magnitude.

Lower informality after governance reforms. Stricter enforcement of government regulations and a better legal framework can increase the costs of remaining in the informal economy (Dabla-Norris, Gradstein, and Inchauste 2008). Anti-corruption

²² From 1996 to 2016, Georgia's global ranking on regulatory quality improved from 150th to 34th place, and its ranking on government effectiveness improved from 123th to 55th place.

efforts and stronger law and order may allow fewer opportunities for informal firms to avoid the obligations of formal firms (Choi and Thum 2005; Dreher and Schneider 2010; Iriyama, Kishore and Talukdar 2016). Better control of corruption can also reduce informality via the tax morale channel (DeBacker, Heim and Tran 2015; Luttmer and Singhal 2014). Empirically, a one-standard-deviation improvement in the control of corruption was associated with a cumulative decrease in output informality by about 0.1 percentage point of GDP in the following three to five years.

Education and training programs

Poorer education associated with greater informality. Informal workers tend to be less skilled, and therefore also less productive, than formal-economy workers (chapter 4; Loayza 2018; Perry et al. 2007). In fact, wage differentials between formal and informal workers have primarily reflected differences in educational backgrounds and experience (box 4.1). Workers in EMDEs with above-median output informality have, on average, one year less of schooling than those in other EMDEs (figure 6.11). Poorer access to schooling and qualified teachers has resulted in significantly poorer education outcomes, measured by PISA test scores, in EMDEs with above-median output informality. Entrepreneurship training, at all levels of education, including education programs aimed at equipping entrepreneurs to create and manage SMEs, are significantly less accessible in EMDEs with above-median output informality.

Over time, improved education and training. Since 1990, education outcomes and skill levels have improved: thus in the average EMDE, average years of schooling have increased by about 2 years (figure 6.11). Entrepreneurship training has also become more accessible in EMDEs, and the improvement has been statistically significantly more pronounced in EMDEs with above-median informality. In some EMDEs, training programs have boosted worker income and firm revenue in the informal sectors (Burki and Abbas 1991; Verner and Verner 2005). These training programs were also supported by general improvements in access to primary education and literacy rates (Aziz et al. 2014; Hathaway 2005).

Lower informality after improvements to training and education. To the extent that workers remain in the informal sector for lack of human capital or skills, better and more accessible public education may help workers (or their dependents) move into better paid formal employment (Andrews, Sánchez, and Johansson 2011; Maloney 2004; Perry et al. 2007).

Empirically, additional entrepreneurship training and improved education outcomes have been accompanied by significant declines in output informality. Five years after a two-standard-deviation increase in access to entrepreneurship training and education at primary and secondary levels, output informality was statistically significantly lower, by 0.2 percentage point of GDP.²³ A 10-point increase in the PISA reading score was

²³Such an improvement was accompanied by a significant reduction in employment informality, by 1.3 percentage points of employment, over 3-4 years.

FIGURE 6.11 Education and informality in EMDEs

Workers in EMDEs with more pervasive informality are, on average, less educated and trained than those in EMDEs with less pervasive informality. Training focused on small and medium-sized enterprises (SMEs) has improved over the past two decades, especially in EMDEs with above-median informality. Better education and training have coincided with declines in informality.

A. Education and informality

B. Education, 1990 vs. 2015

C. Entrepreneurship training and informality

D. Entrepreneurship training, 2000-18

E. Cumulative changes in output informality following a 1-point improvement in basic school entrepreneurial education and training

F. Cumulative changes in output informality following a 10-point increase in national average PISA score on reading

Sources: Barro and Lee (2013); Global Entrepreneurship Monitor; Program for International Student Assessment (PISA) database; World Bank (World Development Indicators).

Note: Data are from emerging market and development economies (EMDEs) and the period 1990-2018. "High (Low) informality" are EMDEs with above (below)-median output informality proxied by dynamic general equilibrium (DGE)-based estimates in percent of GDP. *** denotes that the group differences are not zero at 10 percent significance. All scores regarding entrepreneurship training and education (in C-F) range from 1 (worst) to 4 (best). "Basic school" measures the extent to which training in creating or managing small and medium-sized enterprises (SMEs) is incorporated within the education and training system at primary and secondary levels. "Post school" measures the extent to which training in creating or managing SMEs is incorporated within the education and training system in higher education.

A.C. Bars show simple group averages. PISA scores are for 15-year-old students.

B.D. Bars show simple group averages for corresponding time periods.

E.F. Bars show the cumulative changes in DGE-based output informality in percent of GDP to a 1-point increase in "Basic school" score from the Global Entrepreneurship Monitor (10-point increase in PISA reading scores). Whiskers show the upper and lower bounds of the corresponding 90 percent confidence intervals. "t = n" indicates the cumulative changes in output informality over the n years after a policy change. See annex 6A for detailed model specifications. PISA scores are for 15-year-old students.

associated with a significant decline in output informality, by about 0.1 percentage point of GDP, over the following two years.

Access to finance

Less access to finance in more informal economies. Firms in the informal sector have less access to credit from the banking sector and capital markets, which restricts their ability to invest, including in productivity-enhancing technologies (Capasso and Jappelli 2013; D’Erasmus 2016; Ferreira-Tiryaki 2008; box 6.1; figure 6.12). In EMDEs with above-median informality, about one-third of firms identified access to finance as a major constraint—8 percentage points of firms higher than in EMDEs with below-median informality. Households in EMDEs with below-median informality have access to significantly more commercial bank branches, ATMs, and credit than those in other EMDEs. About half of the population in EMDEs with below-median informality own an account at a financial institution or used a mobile money service recently—about 17 percentage points higher than in EMDEs with below-median informality.

Over time, expanded access to finance. EMDEs, especially in EAP, MNA, SAR and, more recently, SSA, have implemented a series of reforms to improve access to finance. Such reforms mainly aim to strengthen credit reporting systems and improve the effectiveness of collateral and bankruptcy laws (World Bank 2020a). Overall, financial development improved in about 90 out of 142 of EMDEs over the period 2010-2018 (figure 6.12). The number of ATMs per 100,000 adults rose by 50 percent between 2010 and 2018, while the share of population with an account at a financial institution increased from 33 percent to 51 percent. Domestic credit to the private sector increased by about 4 percentage points of GDP over the same period. Access to credit has been facilitated for firms in the informal sector by introducing credit information bureaus and better utilization of information and communication technology (Capasso, Monferrà, and Sampagnaro 2018). Personal property registration has also made loans more accessible for firms operating in the informal economy (for example, in the Czech Republic; World Bank 2012). Digital payment systems have provided an entry point into the formal financial system and encouraged a shift away from informal finance (for example, in Kenya; World Bank 2017).

Lower informality after expanded access to finance. Lower financing costs and easier access to credit can entice informal firms with promising investment projects that require external finance to enter the formal economy (box 6.1). Empirically, adding 10 more bank branches per 100,000 adults was followed by a 0.1-0.3 percentage point decline in the share of informal output in the following 1 to 5 years. A 10-percentage-point-of-GDP increase in domestic credit to the private sector was associated with a significant contraction in output informality, by 0.1 percentage point of GDP over the subsequent 1 to 5 years.

FIGURE 6.12 Access to finance and informality in EMDEs

Firms and workers in EMDEs with more pervasive informality are more likely to be financially constrained, less likely to obtain bank finance, and have limited access to other financial services. Access and depth of financial systems in EMDEs improved between 1990 and 2018. Financial development has been followed by significant declines in output informality.

A. Access to finance and output informality

B. Financial constraints facing firms and output informality

C. EMDEs with improved financial development, 1990-2018

D. Domestic credit to private sector, 1990-2018

E. Cumulative changes in output informality following a 10-unit increase in the number of bank branches per 100,000 adults

F. Cumulative changes in output informality following a 10-percentage-point-of-GDP increase in domestic credit to the private sector

Sources: International Monetary Fund; World Bank.

Note: Data are from emerging market and development economies (EMDEs) and the period 1990-2018. Output informality is measured by dynamic general equilibrium (DGE)-based estimates on informal output (in percent of official GDP). In A-B, *** denotes that the group differences are not zero at 10 percent significance level. See notes below figure B6.1.1 for detailed variable descriptions in A-D. A.B. Bars are unweighted averages for EMDEs with above-median ("high") informality and those with below-median ("low") informality over the period 2010-2018 (A) and 2000-2018 (B). In B, bars are group means using data from latest year available for EMDEs. C.D. Lines show simple EMDEs averages for corresponding time periods. "Overall" is the aggregate financial development index obtained from the IMF. The "Institutions" index subcomponent measures how developed financial institutions are. E.F. Bars show the cumulative changes in DGE-based output informality in percent of GDP to a 1-unit increase in the number of bank branches per 100,000 people (E) or 10-percentage-point-of-GDP increase in domestic credit to the private sector (F). Whiskers show upper and lower bounds of 90 percent confidence intervals. "t = n" indicates n years after the rise in bank branches of private credit. See annex 6A for detailed model specifications.

Conclusion

The COVID-19 pandemic plunged the global economy into an unprecedented contraction in 2020, and it is likely to leave lasting scars on long-term potential output (World Bank 2020b, 2021). Informal sector workers have been among the hardest hit since they are disproportionately employed in the services sector that has been particularly disrupted by the pandemic, work in crowded conditions where the virus can spread easily, and have limited access to savings of government support programs (box 2.1). The limited access to sanitation facilities and medical resources in EMDEs with more pervasive informality illustrates further the development challenges posed by informality. The pandemic has served as a reminder of the longstanding need for policies to address the challenges associated with, and caused by, informality. To achieve the Sustainable Development Goals, policy makers need to boost productivity growth in both formal and informal sectors and reduce the vulnerabilities of firms and workers in the informal economy.

Policies are more likely to succeed in addressing the challenges of informality if they are comprehensive and tailored to country circumstances. Past failures of reforms to lower informality and boost productivity have in part been attributed to reform design that were not tailored to country specifics and not sufficiently embedded in supportive institutional and business environment, in addition to not being consistently implemented (Birdsall, de La Torre, Caicedo 2010; Loayza 2018).

A comprehensive strategy: The right policy mix. Individual policy interventions in isolation may have only a limited impact on informality, and have unwelcome unintended consequences (annex 6A; Oviedo, Thomas, and Karakurum-Özdemir 2009; Ulyseya 2018). A coherent reform strategy is needed, with reforms that complement each other and address the complexity of informality (Loayza 2018). Success also depends on careful monitoring of potential unintended consequences and on a supportive macroeconomic, political and institutional environment. The latter should ensure the political and fiscal viability of reform implementation and reduce the transition costs for workers moving from the informal sector to the formal sector.

A tailored strategy: Addressing economy-specific priorities. Since the causes and features of informality differ considerably across countries, policy makers need to identify economy-specific reform priorities. In countries where informality is predominantly associated with poor governance, a policy package could streamline regulatory and tax frameworks while improving the efficiency of public revenue collection and regulatory enforcement as well as strengthening public service delivery to bolster tax morale. In countries where informality is predominantly a reflection of underdevelopment, a policy package could include expanded access to finance, markets, and inputs to foster firm productivity and growth; better education to facilitate formal sector employment; and enhanced safety nets to cushion household risks. In SSA, SAR, and the non-GCC economies of MNA, for example, general education and training programs to raise human capital could be prioritized (World Bank 2019b; chapter 5). In

LAC, reducing high tax and regulatory costs faced by businesses could incentivize firms to join the formal sector. In ECA, improving government effectiveness and reducing corruption could be policy priorities.

New policy challenges. The emerging “gig” economy poses opportunities and policy challenges with its higher accessibility, more fluid labor arrangements, and greater reliance on digital technology than more traditional forms of informality. Since “gig” workers do not fully participate in the social security system, they are, by some definitions, informal workers (Loayza, Servén, and Sugawara 2010). Regulatory changes, especially in the context of social security systems, can help ensure that “gig” workers’ economic risks are manageable and that they do not permanently lose access to the formal economy (World Bank 2014, 2016, 2018b). Since these workers may take on many different assignments over the course of their careers, the ability to learn and adapt will be essential. Policies can support this adaptability with more provision of education and (re)training programs (Card, Kluve, and Weber 2018; World Bank 2019a). Increased emphasis on the development of cognitive skills in primary and secondary education can also help (Almeida, Behrman, and Robalino 2012; World Bank 2018a, 2018b).

New policy opportunities. New technologies offer governments opportunities both to reduce the incentives for, and increase the cost of, operating informally while also providing boosts to productivity that can propel firms into the formal economy. New technologies can help strengthen tax administration and improve access to finance, including by making it easier to broaden the tax net and assess credit worthiness.²⁴ Digitalization can lower regulatory burdens. For example, Costa Rica reduced the time required to register a business by digitizing tax registration records and company books in 2009 (World Bank 2009). This was followed by a drop in informal employment by 4 percentage points of total employment and a fall in informal output by about 2 percentage points of official GDP during 2009-16 (World Bank 2019b). Similar reforms have been carried out in Guyana (2010) and Kenya (2011; World Bank 2010, 2011).

Safeguarding informal workers during severe shocks. COVID-19 has taken an especially heavy humanitarian and economic toll on EMDEs with large informal sectors (World Bank 2020b). The vulnerabilities of the informal sector, associated with low incomes and limited access to government benefits and public services, have amplified the economic shock from COVID-19 and the related threat to livelihoods (OECD 2020). In many countries, the pandemic has revealed severe shortcomings in social security systems and governments’ ability to support vulnerable groups (Loayza and Busso et al. 2020; Pennings 2020).²⁵ Despite their high costs, untargeted programs may be warranted during such a crisis to maximize the reach to informal-economy

²⁴ See Awasthi and Engelschalk (2018); Capasso, Monferrà, and Sampagnaro (2018); Gupta et al. (2017); and Junquera-Varela et al. (2017).

²⁵ See Fang, Kennedy, and Resnick (2020) for a review of social protection policies implemented under COVID-19.

participants; their long-term fiscal burden can be minimized by prioritizing temporary and reversible measures. To prevent hysteresis in formal-sector job losses, policies can aim to preserve formal-sector employment opportunities while protecting the poor and informal workers through food aid and cash transfers (Alfaro, Becerra, and Eslava 2020).

Future research. Some policy areas remain under-explored in the literature. First, digitalization is a recent development in EMDEs that holds great potential for informal-economy participants and policy makers. Yet little is known about the impact of digitalization of government services or private economic activity on the informal economy, including relative to the formal economy. The possibility that digitalization will disproportionately benefit formal firms, and thus shrink the relative size of the informal sector, deserves examination. Second, past studies have focused on the impact of policies on formalization without looking into their effects on the resilience of the informal economy. Future studies could examine policies that can improve the resilience of the informal economy and prevent informal participants from being tipped into poverty by negative shocks such as COVID-19. Lastly, the chapter has not touched upon some emerging ideas regarding how governments can better engage with informal businesses, such as providing a simplified, intermediate and temporary legal status to informal businesses that could be aligned with both business needs and government goals (Marusic et al. 2020).

ANNEX 6A Policies and informality

The linkage between policies and informality is analyzed via the local projection model. It focuses on showing the cumulative change in informality following policy changes.

Definitions

Both output informality and employment are considered in the regression analyses here. Output informality is proxied by dynamic general equilibrium (DGE)-based estimates in percent of official GDP, and employment informality is proxied by self-employment in percent of total employment. Both measures cover up to 125 EMDEs over the period 1990-2018. For the estimation of the local projection model, all data series are detrended using the Hodrick-Prescott (HP) filter.

Policy indicators

The following policy measures were considered, covering up to 121 EMDEs for 1990-2018 (table 6.2).²⁶

Tax rates. Corporate, individual, and value-added tax rates from Végh and Vuletin (2015; updated to 2019) using data from OECD, University of Michigan, and KPMG.

²⁶ While the data for some indicators are available for more than 121 EMDEs, the regressions cover up to 121 EMDEs.

Cost of tax compliance. Ease of paying taxes score from the World Bank's *Doing Business* database (World Bank 2020a; 0 = worst and 100 = best);

Access to finance. Domestic credit to the private sector in percent of GDP, a common measure for depth of financial institutions, is provided by World Development Indicators (World Bank 2020c); the number of commercial bank branches per 100,000 adults, a common measure for the access to financial institutions, is obtained from Global Financial Development Database (World Bank 2019c);

Labor market regulation. Labor market efficiency index from World Economic Forum's Global Competitiveness Report (ranging from 1 to 7 with a higher score indicating a more efficient labor market) and the index for hiring and firing regulation from Fraser Institute (Fraser Institute 2020; 1 = firing and hiring are most determined by regulations but not by the employer, 10 = firing and hiring are mostly determined by the employer but not by regulations).

Governance. Bureaucracy quality, control of corruption, and law and order are from the *International Country Risk Guide* (ICRG; 1 = worst governance, 4/6 = best governance).

Government services. Survey responses on the presence and quality of programs directly assisting SMEs at all levels of government (national, regional, municipal: "government programs) and on the presence of property rights, commercial, accounting and other legal and assessment services and institutions that support or promote SMEs ("Commercial and professional infrastructure"), taken from the National Expert Surveys of the Global Entrepreneurship Monitor for the period 2000-19 (ranging from 1 to 4 with a lower score representing poorer entrepreneurial conditions). Survey responses on the extent to which training in creating or managing SMEs is incorporated within the education and training system at primary and secondary levels ("basic school") are also taken from the National Expert Surveys of the Global Entrepreneurship Monitor. Mobile phone subscriptions per 100 people are taken from World Development Indicators.

Firm start-up costs. Cost of business start-up procedures in percent of GNI per capita and time required to start a business in days are from *Doing Business* (World Bank 2020a).

Education and health outcomes. Life expectancy at birth and PISA test scores for reading (students aged 15) are from World Development Indicators (World Bank 2020c).

Model specification: The local projection model

A local projection model as in Jordà (2005), Teulings and Zubanov (2014), and World Bank (2018c) is used to identify the effects of policy changes on informality over time. In impulse responses, the model estimates the effect of policy changes on cumulative changes in the cyclical component of (DGE-based) informal output in percent of official

FIGURE 6A.1 Robustness checks: Evolution of informal output levels following financial development in EMDEs

Similarly to the results on ratios of informality, improved access and depth of financial institutions are linked with significant contractions in levels of informal output in the following years.

A. Cumulative changes in informal output levels following a 10-unit increase in the number of bank branches per 100,000 people

B. Cumulative changes in informal output levels following a 10-percentage-point-of-GDP increase in domestic credit to the private sector

Source: World Bank.

Note: Data for the period 1990-2018 and EMDEs. Here informal output level is measured by dynamic general equilibrium (DGE)-based estimates on informal output (in constant 2011 USD). The results are obtained via a local projection method where informality measures are detrended using Hodrick-Prescott (HP) filter. See annex 6A for detailed model specifications. A-B. Bars show the cumulative changes in DGE-based output informality in percent of GDP following a 10-unit increase in the number of bank branches per 100,000 people (A) and 10-percentage-point-of-GDP increase in the share of domestic credit to the private sector in percent of GDP (B). Whiskers show the upper and lower bounds of the corresponding 90 percent confidence intervals. "t = n" indicates the cumulative changes in output informality over the n years after a policy change.

GDP (or self-employment in percent of total employment) over a time horizon h while controlling for country fixed effects and per capita income levels:²⁷

$$y_{i,t+h} - y_{i,t-1} = \alpha^h + \beta^h d.policy_{i,t-1} + \theta^h X_{i,t} + fixed\ effects + \epsilon_{i,t}^h$$

where $y_{i,t}$ is the cyclical component of informality in country i and year t . The variable $d.policy_{i,t-1}$ is the variable of interest, which measures the change in policy indicators in country i and year $t-1$. The policy change variable is lagged here to deal with potential endogeneity issues. Real GDP per capita (constant 2010 US dollars, obtained from World Development Indicators 2020) is included as the control variable (i.e. $X_{i,t}$).²⁸ Results are shown in tables 6.4-6.5.

²⁷ The results are robust to using levels of DGE-based informal output (figure 6A.1).

²⁸ In the case of corporate and individual tax rates, the levels of both tax rates at year t in country i are also included as control variables. The results do not change when these two control variables are dropped. Similarly, when labor tax and contributions is the variable of interest, the level of labor tax and contributions at year t in country i is included as one of the control variables.

TABLE 6.1 A summary of empirical studies on financial development and informality

Paper	Measure of financial development (FD).	Measure of the informal economy (IE)	Estimators	Main database	Results
Gatti and Honorati (2008)	Access to credit, indicating whether the firm has a credit or overdraft line.	Percentage of firms' sales reported to tax authority.	OLS and FE (fixed effects) estimation.	World Bank investment climate surveys.	Less informality is robustly and significantly related with more access to credit. Moreover, the relationship between credit and formality is stronger in high-formality countries.
Dabla-Norris and Inchauste (2008)	Private credit over deposit money at banks and other financial institutions as a share of GDP.	Percent of sales not reported to tax authorities.	OLS with clustered standard errors.	The 2005 Business Environment and Enterprise Performance Survey of the World Bank and the European Bank for Reconstruction and Development.	Firms that rate financing as major obstacles to their business have, on average, a 16 percent probability of hiding 50 percent of their sales.
Bose, Capasso, and Wurm (2012)	Liquid liabilities and total domestic credit provided by depository banks, bank overhead costs, net interest margin, lending-deposit rate spread, and level of bank concentration. All as a percentage of GDP.	Percent of sales not reported to tax authorities DYMIMIC method (Schneider 2007) and WEF (World Economic Forum) measure.	FE (fixed effects) and GMM (generalized method of moments).	Beck, Demirgüç-Kunt, and Levine (2000) database and the World Bank World Development Indicators (WDI).	Improvement in the depth and efficiency of the banking sector leads to a smaller informal economy.
Elgin and Uras (2013)	Money and quasi money, domestic credit provided by financial corporations to the private sector, domestic credit from the financial sector, and net credit to central government.	DYMIMIC approach (Schneider 2007).	GMM	World Bank (WDI).	A non-linear inverse-U relationship between financial development and shadow economy size.
Capasso and Jappelli (2013)	Probability of being credit-rationed (Guiso, Sapienza, and Zingales 2004).	Irregular job rate Share of income paid in cash.	OLS and instrumental variables estimation.	Bank of Italy's Survey of Households Income and Wealth (SHIW).	Negative and significant effect of financial development on the measure of informal economy. The impact is particularly strong in construction but also in the retail and tourism sectors.

TABLE 6.1 A summary of empirical studies on financial development and informality (continued)

Paper	Measure of financial development (FD).	Measure of the informal economy (IE)	Estimators	Main database	Results
Bittencourt, Gupta and Stander (2014)	Domestic credit over GDP; interest rate differential between loans and deposits; liquid liabilities as a percentage of real GDP; market capitalisation of all listed companies as a percentage of real GDP.	DYMIMIC approach (Schneider 2010) and Dynamic general equilibrium (DGE) model (Elgin and Öztunali 2012).	FE and GMM	Schneider et al. 2010; Elgin and Öztunali 2012; World Bank WDI, Global Development Finance, and World Governance Indicators (WGI).	Lower (higher) levels of financial development and higher (lower) levels of inflation lead to a higher (lower) size of the shadow economy.
Berdiev and Saunoris (2016)	Money and quasi money (M2) as percentage of GDP; domestic credit provided by financial corporations to the private sector (private credit) as a percentage of GDP; and domestic credit from the financial sector to various sectors and net credit to the central government (financial credit) as percentage of GDP	Dynamic general equilibrium (DGE) model (Elgin and Öztunali 2012).	GMM and panel vector autoregression (VAR) analysis	World Bank's World Development Indicators and Elgin and Öztunali (2012).	A shock to M2 reduces the size of the shadow economy, and this effect becomes insignificant after eight years. A shock to the shadow economy shrinks financial development.
Bayar and Öztürk (2016)	Domestic credit to private sector.	DYMIMIC approach (Schneider, Raczkowski, and Miröz 2015).	Cointegration analysis	Schneider, Raczkowski, and Miröz (2015), World Bank and Heritage Foundation.	Financial development and improvements in institutional quality reduce the size of the shadow economy, in the long run.
Canh and Thanh (2020)	Overall financial development, overall financial institutions, overall financial markets, financial institutions' depth, financial institutions' access, financial institutions' efficiency, financial markets' depth, financial markets' access, and financial markets' efficiency.	DYMIMIC approach (Medina and Schneider 2018).	Dynamic fixed effects—autoregressive distributed lag	Medina and Schneider (2018), Svirydzenka (2016), World Bank WDI and WGI; Heritage Foundation	Non-linear negative relationship between financial development and shadow economy for eight out of the nine financial indicators.
Gharleghi and Jahanshahi (2020)	Liquid liabilities, private credit and stock market capitalisation.	MIMIC and PMM (Predictive Mean Matching) method (Medina and Schneider 2018).	Threshold FE.	World Bank WDI and global financial development.	Financial development has a negative and significant effect on the shadow economy, but only for countries that have a per capita GDP of US\$33,600 and higher.

Sources: Global Entrepreneurship Monitor; International Country Risk Guide (ICRG); KPMG; University of Michigan; Organisation for Economic Co-operation and Development; Végh and Vuletin (2015); World Bank (*Doing Business*, World Development Indicators); World Value Surveys; World Economic Forum (WEF).

Note: Data are from emerging market and development economies (EMDEs) averaged over the period 1990-2018 (or otherwise specified). All regressions here use the same sample of data as in figures 6.2-6.12, please see details above. The cells show the coefficients of regressing various policy measures (listed in the first column on the left) against the share of informal output (dynamic general equilibrium estimates) in percent of official GDP, with standard errors shown in parentheses. * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$.

Note: Data are from emerging market and development economies (EMDEs) averaged over the period 1990-2018 (or otherwise specified). All regressions here use the same sample of data as in figures 6.2-6.12, please see details above. The cells show the coefficients of regressing various policy measures (listed in the first column on the left) against the share of informal output (Dynamic General Equilibrium estimates) in percent of official GDP, with standard errors shown in parentheses. * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$.

ECO-AUDIT

Environmental Benefits Statement

The World Bank Group is committed to reducing its environmental footprint. In support of this commitment, we leverage electronic publishing options and print-on-demand technology, which is located in regional hubs worldwide. Together, these initiatives enable print runs to be lowered and shipping distances decreased, resulting in reduced paper consumption, chemical use, greenhouse gas emissions, and waste.

We follow the recommended standards for paper use set by the Green Press Initiative. The majority of our books are printed on Forest Stewardship Council (FSC)-certified paper, with nearly all containing 50-100 percent recycled content. The recycled fiber in our book paper is either unbleached or bleached using totally chlorine-free (TCF), processed chlorine-free (PCF), or enhanced elemental chlorine-free (EECF) processes.

More information about the Bank's environmental philosophy can be found at <http://www.worldbank.org/corporateresponsibility>.

A large percentage of workers and firms operate in the informal economy, outside the line of sight of governments in emerging markets and developing economies. This may hold back the recovery in these economies from the deep recessions caused by the COVID-19 pandemic—unless governments adopt a broad set of policies to address the challenges of widespread informality. This study is the first comprehensive analysis of the extent of informality and its implications for a durable economic recovery and for long-term development. It finds that pervasive informality is associated with significantly weaker economic outcomes—including lower government resources to combat recessions, lower per capita incomes, greater poverty, less financial development, and weaker investment and productivity.

By definition, the informal economy is hard to study, especially in developing countries. This excellent book uses state-of-the-art methodologies and recently available data to measure and analyze informality in advanced economies and emerging market and developing economies. In particular, it explores the business cycles in the informal sector in 160 countries over the last 30 years; the study is the first one to show that cycles in the formal economy cause those in the informal economy. Contrary to the widespread stereotype that the informal sector is a buffer that helps to mitigate recessions in the formal sector, the informal sector's output moves in sync with the formal one, and informal employment does not increase during recessions. The book also produces the first analysis of the role of informality during the COVID pandemic. Informal economic activity is concentrated in labor-intensive service sectors and thus is especially vulnerable to social distancing and lockdowns. A rigorous, relevant and highly timely must-read for development scholars and policy makers.

Sergei Guriev

Professor of Economics, Sciences Po, and
Former Chief Economist, European Bank for Reconstruction and Development

Significant data gaps have previously limited our ability to thoroughly study the informal economy until now. The authors construct a novel and comprehensive dataset on informality, which allows them to unpack the complexity of the informal sector and its interaction with the formal sector. This timely book provides an invaluable knowledge resource for researchers and practitioners alike through an approach that balances rigorous quantitative and qualitative methods. The resulting policy recommendations offer compelling pathways for policy makers looking to address some of the main obstacles to formalization of the economies and accelerate economic development in the post-pandemic world.

Brahima Sangafowa Coulibaly

Vice President, Global Economy and Development
